“...What the eyes perceive in herbs or stones or trees is not yet a remedy;

the eyes see only the dross. But inside, under the dross,

there the remedy lies hidden.

First it must be cleaned from the dross, then it is there.

This is alchemy, and this is the office of Vulcan;

he is the apothecary and chemist of the medicine...”

Paracelsus (1493 – 1541)

SUMMARY

Tropical parasitic diseases such as malaria, human African trypanosomiasis, chagas disease, and leishmaniasis affect hundreds of millions of people worldwide and have devastating consequences. Current drugs available to treat these diseases have serious drawbacks. New drugs are urgently needed.

Natural products (NPs) play a dominant role in drug discovery for the treatment of human diseases. Particularly, quinine and artemisinin have their origin in nature and have inspired successful drugs for malaria treatment.

In a medium throughput screening, a total of 507 extracts from South African plants were assayed for their antiprotozoal activity against *Plasmodium falciparum*, *Trypanosoma brucei rhodesiense*, *Trypanosoma cruzi* and *Leishmania donovani*. Extracts from *Abrus precatorius* L. ssp. *africanus* Verdc. (Fabaceae) and *Drypetes gerrardii* Hutch. var. *gerrardii* (Putranjivaceae) inhibited at least one of the parasites at a test concentration considered relevant. With the aim of identifying the compounds responsible for these activities, a HPLC-based activity profiling approach followed by dereplication was applied. Targeted isolation of promising compounds was achieved by a combination of chromatography techniques. Structure elucidation was achieved by HR-ESI-MS and NMR (^1H , ^{13}C , COSY, HMBC, HSQC, and NOESY spectroscopy). Absolute configuration was determined by comparison of electronic circular dichroism (ECD) spectra with calculated ECD data.

HPLC-based activity profiling of *A. precatorius* allowed the identification of abruquinones, a series of isoflavan quinones, as responsible for the trypanocidal activity of the crude extract. A total of ten abruquinones were isolated. Among these were five new compounds, and one compound was reported for the first time as natural product. Abruquinone B, I, A, D, K, and L showed remarkable inhibition (0.16 ± 0.060 , 0.28 ± 0.051 , 0.02 ± 0.003 , 0.01 ± 0.001 , 0.11 ± 0.053 , and 0.02 ± 0.053 , respectively) and notable selectivity, expressed as selectivity indices (SIs) which were calculated from cytotoxicity data in L-6 cells (51, 74, 1379, 668, 508, and 374, respectively). These results warrant *in vivo* assessment of abruquinones.

Abruquinones are promising hits due to their strong and selective *in vitro* inhibition of *T. b. rhodesiense*, their good compliance with Lipinski's "rule-of-5" and other molecular properties, as well as their predicted low/moderate toxic potential. Therefore, further studies are necessary to guarantee a botanical or chemical source, and to assess *in vivo* efficacy.

Two different extracts of *D. gerrardii* showed antiprotozoal activity, and the active constituents were tracked and isolated by HPLC-based activity profiling. The $\text{CH}_2\text{Cl}_2/\text{MeOH}$ (1:1) stems extract inhibited *L. donovani* and *P. falciparum*. The major compound, a new phenanthrenone, showed good *in vitro* activity

(IC₅₀ of $0.9 \pm 0.3 \mu\text{M}$) and selectivity (SI of 68) against *P. falciparum*. Based on these promising results, *in-vivo* studies were conducted. However, the compound was not able to reduce parasitemia in the *P. berghei* mouse model. A phenanthrenone heterodimer was also isolated and showed *in vitro* antiplasmodial activity (IC₅₀ of $2.04 \pm 0.15 \mu\text{M}$ and SI of 31). Furthermore, the CH₂Cl₂/MeOH (1:1) leaves extract displayed trypanocidal properties, and the known saponin putranoside A was isolated and tested against *T. b. rhodesiense*, (IC₅₀ of $18.0 \pm 3.8 \mu\text{M}$ and a SI of 4).

The phenanthrenone was the most active and selective *in vitro* inhibitor of *P. falciparum*, but showed no inhibition *in vivo* against *P. berghei*. However, the compound fulfilled Lipinski's "rule-of-5" and other molecular properties, which indicates a potential to meet requirements of an ideal antimalarial drug such as, oral bioavailability and blood-brain barrier permeability. According to Medicines for Malaria Venture compound progressing criteria, the phenanthrenone complies with some of the features of a validated hit such as sufficient activity against *P. falciparum in vitro* ($< 1 \mu\text{M}$). The assessment of *in vivo* activity in additional animal models, e.g. *Pf*-huMouse model could be considered for compound progression in the drug discovery pipeline.

Additionally, as part of a project aimed at investigating antiprotozoal European plants *Chrysanthemum cynerariifolium* (Trevir.) Vis. (Asteraceae), *Laurus nobilis* L. (Lauraceae), and *Eupatorium cannabinum* L. (Asteraceae) were studied. A hexane extract of *C. cynerariifolium* showed promising activity against *P. falciparum*. Pyrethrins (irregular monoterpenes) were the metabolites responsible for the antiplasmodial activities. Particularly, pyrethrin II and jasmolin II inhibited *P. falciparum* (IC₅₀ $4.0 \pm 1.1 \mu\text{M}$ and $5.0 \pm 0.4 \mu\text{M}$, respectively and SI of 24 and 6, respectively) *in vitro*. Synthetic pyrethroids were also tested, but they did not show activity. However, none of the two compounds fulfilled activity and selectivity requirements for *in vivo* evaluation.

Finally, as a contribution to the structure activity relationship study of sesquiterpene lactones showing activity against *T. b. rhodesiense*, costunolide and zaluzanin D were isolated from *Laurus nobilis* L. (Lauraceae) and eupatoriopicrin from *Eupatorium cannabinum* L. (Asteraceae). Germacrolides, i.e. costunolide and eupatoriopicrin, showed a higher inhibition (IC₅₀ of $1.3 \pm 0.4 \mu\text{M}$ and $1.2 \pm 0.2 \mu\text{M}$, respectively) on the protozoon, than the guaianolide zaluzanin D (IC₅₀ of $10.8 \mu\text{M}$). However, none of the sesquiterpene lactones showed sufficient activity and selectivity to warrant *in vivo* testing.

In brief, a total of 22 secondary metabolites were isolated from five species. Among them, seven new compounds were discovered. These compounds belong to the structural classes of isoflavonoids, phenanthrenones, and terpenes such as, sesquiterpene lactones, irregular monoterpenes and triterpenoid

saponins. Most of them (15 compounds) exhibited *in vitro* antiprotozoal activity, albeit at differing extent. The most promising compounds were the abruquinones and the phenanthrenone, which strongly and selectively inhibited *T. b. rhodesiense* and *P. falciparum*, respectively. Abruquinones and the phenanthrenone are drug-like compounds with a calculated toxic potential ranging from low to moderate.

ZUSAMMENFASSUNG

Tropische parasitäre Krankheiten wie Malaria, afrikanische Trypanosomiasis (Schlafkrankheit), Chagas-Krankheit und Leishmaniose betreffen Hunderte von Millionen Menschen weltweit und haben verheerenden Folgen. Aktuelle Medikamente, die zur Behandlung dieser Krankheiten zur Verfügung stehen, haben gravierende Nachteile. Neue Medikamente werden dringend benötigt.

Naturstoffe (NP) spielen eine dominierende Rolle in der Wirkstoffforschung für die Behandlung von menschlichen Erkrankungen. So haben Chinin und Artemisin ihren Ursprung in der Natur und führten zu erfolgreichen Medikamenten zur Malariabehandlung.

In einem mittleren Durchsatz-Screening wurden insgesamt 507 Extrakte von südafrikanischen Pflanzen auf ihre Aktivität gegen Protozoen - *Plasmodium falciparum*, *Trypanosoma brucei rhodesiense*, *Trypanosoma cruzi* und *Leishmania donovani* - getestet. Extrakte von *Abrus precatorius* L. ssp. *africanus* Verdc. (Fabaceae) und *Drypetes gerrardii* Hutch. var. *gerrardii* (Putranjivaceae) haben mindestens einen der Parasiten in einer als relevant bezeichneten Testkonzentration gehemmt.

Mit dem Ziel die für diese Aktivitäten verantwortlichen Verbindungen zu identifizieren wurde ein Ansatz bestehend aus HPLC-basiertes Aktivitäts-Profiling gefolgt von Dereplikation verwendet. Gezielte Isolierung der vielversprechenden Verbindungen erfolgte durch eine Kombination von Chromatographie-Techniken. Die Strukturaufklärung wurde durch HR-ESI-MS und NMR (^1H , ^{13}C , COSY, HMBC, HSQC, und NOESY Spektroskopie) durchgeführt. Die absolute Konfiguration wurde durch den Vergleich der elektronischen Zirkulardichroismus-(ECD)-Spektren mit berechneten ECD-Daten bestimmt.

HPLC-basiertes Aktivitäts-Profiling von *A. precatorius* ermöglichte die Identifizierung von Abruquinonen, einer Reihe von Isoflavan-Chinonen, als verantwortliche Substanzen für die trypanozide Aktivität des Rohextrakts. Es wurden insgesamt 10 Abruquinone isoliert, darunter fünf neue Verbindungen. Eine Verbindung wurde zum ersten Mal als Naturstoff beschrieben. Abruquinone B, I, A, D, K und L zeigten bemerkenswerte Hemmung (0.16 ± 0.060 , 0.28 ± 0.051 , 0.02 ± 0.003 , 0.01 ± 0.001 , 0.11 ± 0.053 , und 0.02 ± 0.053) und beachtenswerte Selektivität, wiedergegeben als Selektivitätsindizes (SIs) die aus der Zytotoxizität in L-6 Zellen (51, 74, 1379, 668, 508, und 374) ermittelt wurden. Diese Ergebnisse rechtfertigen eine Prüfung der *in vivo*-Aktivität von Abruquinonen.

Wegen ihrer starken und selektiven *in vitro* Hemmung von *T. b. rhodesiense*, ihrer guten Übereinstimmung mit Lipinski's „5er Regel“ und anderen molekularen Eigenschaften, sowie ihrem niederen/mässigen toxischen Potenzial sind Abruquinone vielversprechende Hits. Deshalb sind weitere

Studien notwendig um botanische oder chemische Quellen sicherzustellen und die *in-vivo* Wirksamkeit dieser Verbindungen zu bestimmen.

Zwei verschiedene Extrakte von *D. gerrardii* zeigten Aktivität gegen Protozoen. Die aktiven Bestandteile wurden mit Hilfe vom HPLC-basiertem Aktivitäts-Profilings identifiziert und isoliert. Der CH₂Cl₂/MeOH (1:1) Extrakt aus den Stängeln hemmte *L. donovani* und *P. falciparum*. Die Hauptverbindung, ein neues Phenanthrenon, zeigte gute *in vitro* Aktivität (IC₅₀ von $0.9 \pm 0.3 \mu\text{M}$) und Selektivität (SI von 68) gegen *P. falciparum*. Basierend auf diesen vielversprechenden Resultaten wurden *in vivo* Studien durchgeführt. Allerdings war diese Verbindung nicht in der Lage die Parasitenbelastung im *P. berghei* Mausmodell zu reduzieren. Es wurde ebenfalls ein Phenanthrenon-Heterodimer isoliert, der *in vitro* Aktivität gegen Plasmodien (IC₅₀ von $2.04 \pm 0.15 \mu\text{M}$ und SI von 31) aufwies. Ausserdem zeigte der CH₂Cl₂/MeOH (1:1) Blattextrakt ausgewiesene trypanozidale Eigenschaften. Aus diesem Extrakt wurde das bekannte Saponin Putranoside A isoliert und gegen *T. b. rhodesiense*, (IC₅₀ von $18.0 \pm 3.8 \mu\text{M}$ und SI von 4) getestet.

Das Phenanthrenon war der aktivste und selektivste *in vitro* Inhibitor von *P. falciparum*, zeigte jedoch keine Hemmung *in vivo* gegen *P. berghei*. Die Verbindung erfüllte jedoch Lipinski's „5er Regel“ und andere molekulare Eigenschaften, wie orale Bioverfügbarkeit und Durchlässigkeit der Blut-Hirn-Schranke, was ein mögliches Potenzial aufzeigt den Anforderungen eines idealen Antimalariawirkstoffs gerecht zu werden. Nach „Medicines for Malaria Venture“-Kriterien für die weitere Entwicklung eines Wirkstoffs erfüllt das Phenanthrenon einige der Merkmale eines validierten Hits wie ausreichende *in vitro* Aktivität gegen *P. falciparum* ($< 1 \mu\text{M}$). Die Bewertung der *in vivo* Aktivität in weiteren Tiermodellen, z.B. *Pf*-huMaus-Modell könnte für den weiteren Wirkstoffentwicklungsprozess in Betracht gezogen werden.

Als weiterer Teil des Projekts wurde die Wirkung von europäischen Heilpflanzen *Chrysanthemum cynerariifolium* (Trevir.) Vis. (Asteraceae), *Laurus nobilis* L. (Lauraceae), und *Eupatorium cannabinum* L. (Asteraceae) gegen Protozoen studiert. Ein Hexan-Extrakt von *C. cynerariifolium* zeigte vielversprechende Aktivität gegen *P. falciparum*. Phyrethrine (unregelmässige Monoterpene) waren die Inhaltsstoffe verantwortlich für die antiplasmodiale Aktivität. Besonders Pyrethrin II und Jasmolin II hemmten *P. falciparum* (IC₅₀ $4.0 \pm 1.1 \mu\text{M}$ und $5.0 \pm 0.4 \mu\text{M}$, und SI von 24 und 6) *in vitro*. Es wurden auch synthetische Pyrethroide getestet, sie zeigten aber keine Aktivität. Keiner der beiden Wirkstoffe erfüllte die Anforderungen an Aktivität und Selektivität für *in vivo* Evaluierung.

Schliesslich, als Beitrag zu den Struktur-Aktivitätsuntersuchungen von Sesquiterpenlactonen mit Aktivität gegen *T. b. rhodesiense*, wurden Costunolid und Zaluzanin D aus *Laurus nobilis* L. (Lauraceae) und Eupatoriopicrin aus *Eupatorium cannabinum* L. (Asteraceae) isoliert. Germacrolides, d.h. Costunolid und Eupatoriopicrin, zeigten eine höhere Hemmung (IC_{50} von $1.3 \pm 0.4 \mu M$ und $1.2 \pm 0.2 \mu M$) auf Protozoen als das Guaianolid Zaluzanin D (IC_{50} von $10.8 \mu M$). Keines der Sesquiterpenelactone zeigte ausreichende Aktivität und Selektivität für *in vivo* Tests.

Es wurden insgesamt 22 Sekundärmetaboliten aus fünf Arten isoliert, darunter sieben neue Verbindungen. Diese Substanzen gehören zu den Strukturklassen der Isoflavonoide, Phenanthrenone und Terpene einschliesslich Sesquiterpenelactone, unregelmässige Monoterpene und Triterpenoidsaponine. Die meisten von ihnen (15 Verbindungen) zeigten *in vitro* Aktivität gegen Protozoen wenn auch in unterschiedlichem Ausmass. Die vielversprechendsten Verbindungen waren die Abruquinone und das Phenanthrenon, die starke und selektive Hemmung gegen *T. b. rhodesiense* und *P. falciparum* zeigten. Abruquinone und das Phenanthrenon sind drug-like Verbindungen mit einem rechnerischen toxischen Potential von gering bis mässig.

1. AIM OF THE WORK

Tropical parasitic diseases blight the lives of hundreds of millions of people worldwide and result in significant mortality. The social and economic consequences are devastating [1, 2]. Malaria, human African trypanosomiasis (HAT), Chagas disease, and leishmaniasis accounted in 2011 for estimated 669.274 deaths and 61.012.393 disability-adjusted life years (DALYs) [3, 4]. Most of the drugs available to treat these diseases have serious drawbacks in efficacy, show severe side effects, poor patient compliance, and resistance [2, 5]. Hence, new drugs are urgently needed [6-8].

Natural products (NPs) play a dominant role in drug discovery for the treatment of human diseases [9, 10]. Particularly, several well-established antiprotozoal drugs such as quinine and artemisinin have their origins in nature [11]. In fact, the history of antimalarial drug discovery contributed fundamentally to the modern concept of chemotherapy [12].

The aim of this work was to find hit compounds from medicinal plants and to determine their potential for future optimization as a part of a drug discovery program attempting to develop drugs intended for the treatment of parasitic tropical diseases.

As a first step, 118 South African plant species, belonging to 69 botanical families were selected mainly based on their traditional use. The plants were recollected and three extracts were obtained by successive extraction with solvents of increasing polarity. The resulting 507 extracts were formatted into a focused extract library.

The extracts were screened in a medium throughput platform against *Plasmodium falciparum*, *Trypanosoma brucei rhodesiense*, *Trypanosoma cruzi*, and *Leishmania donovani*, causative agents of malaria, HAT, chagas disease, and leishmania, respectively. Every extract was assayed in two concentrations and the most active ones (>95% inhibition at 10 $\mu\text{g/mL}$) were subjected to IC_{50} determination. Extracts with an IC_{50} values $\leq 5 \mu\text{g/mL}$ were considered to be active. To select extracts for further investigation, activity, potential structural novelty of substances contained in the extract, and taxonomic criteria of the plant were considered.

Selected extracts had to be fractionated in microgram amounts and in parallel, on-line spectroscopic (PDA), spectrometric (ESI-MS), and ELSD data had to be recorded. Collected one-minute fractions had to be re-assayed against the corresponding parasites. Biological results, chromatograms, and analytical data are combined to obtain a HPLC-based activity profiling [13-15]. Dereplication is supported with natural product databases, SciFinder Scholar, and other bibliographic resources to prioritize the extracts [16].

Subsequently, constituents responsible for the activity had to be isolated in small amounts (1 - 5 mg) for structure elucidation and *in vitro* antiprotozoal assessment. Compounds which comply with acceptance criteria for activity, selectivity, and novelty, are classified for *in vivo* evaluation in primary rodent models.

2. INTRODUCTION

2.1 Natural Products and Drug Discovery

2.1.1 Historical Background

Medicinal plants have been used since the dawn of mankind to alleviate and treat diseases [1-3]. Pre-hellenic civilizations documented their knowledge in different kind of documents.

The Sumerian healers recorded the knowledge about medicinal agents, mostly plants, in more than 600 tablets of clay, written around 1700 BC [4]. The registers contain information regarding the used formulations, plant decoctions and other preparations [3, 4].

Ancient Egyptians listed in the Ebers Papyrus more than 800 prescriptions. This document dates back to around 1550 BC and describes remedies for skin, ocular, and gastrointestinal complaints. Most of the prescriptions include culinary plants, such as grapes, figs, wheat, and spices (coriander, caraway, fennel, peppermint, and thyme). Furthermore, fragrant resins of *Boswellia ssp.* (frankincense) and *Commiphora myrrh* (myrrh) were highly valued by Egyptian embalmers. In Egypt, the physicians were priests. At that time, elements of religion and magic were closely intertwined with use of herbal drugs [1, 3, 4].

In India, one of the most traditional systems of medicine is the Ayurveda. The word Ayurveda is derived from the Sanskrit word “*Ayus*” (all aspects of life from birth to death) and “*Veda*” (knowledge or science), meaning science of long life. In the Vedic time, treatment of diseases was done by specific persons called ascetic people. They transmitted their knowledge to the next generations in three books called “*Brihat Trayees*” (major three), written between 1000 BC to 7th AD. These books contain basic concepts of health, disease, herbal formulations, and the description of about 900 plant species. One of the best known plant in western culture is *serpaghanda*, *Rauwolfia serpentina*, which contains the antihypertensive and antipsychotic alkaloid reserpine [3-5].

Chinese knowledge in medicinal plants was collected in treatises called “*Bencao*”. The first one appeared during the late Han dynasty (206 BC - 200 AD). However, the most comprehensive and best known treatise is the “*Bencao*” *Gangmu* or “Systematic Materia Medica”, compiled during the Ming dynasty (1518 - 1596 AD) [4, 6, 7]. One of the most valued Chinese medicinal plants is *Ginkgo biloba*, used to improve the memory and to sharpen mental alertness. The main constituents responsible for these effects are reported to be the ginkgolides and flavonoids. *Panax ginseng* is reported to maintain health. Its main constituents are saponins (ginsenosides). The number of medicinal plants currently used in China is larger than 5.000 [1, 3].

Most of the ancient civilizations explained illness as a supernatural phenomenon, and healing as an art related to magic and religion. However, the Greeks changed this, and supernatural beliefs were rejected in favor of rational concepts. They postulated that diseases were caused by an imbalance in body humors (blood, phlegm, yellow bile, and black bile). Consequently, finding drugs became based on the belief that they had to correct this imbalance. These ideas were mentioned for the first time in the “*Hippocratic Corpus*”, a written work comprised of about 60 treatises, attributed to Hippocrates (born in Cos 460 or 450 BC). Moreover, from the Greek time the book “*Historia Plantarum*”, written by Theophrastus (ca. 370 - 287 BC), a former student of Aristotle (384 - 322 BC), classified and described more than 500 plants [3, 4].

In Rome, Dioscorides (ca. 40 - 90 AD) wrote “*De Materia Medica*”, the major source of information about medicinal herbs used in the Hellenic world, in which he cited more than 600 plants. He provided a description of each herb and its habitat, discussed its humoral qualities and its characteristics so that adulteration could be recognized. Dioscorides also reported side effects. Amongst others, he described belladonna, cassia, cinnamon, cumin, fennel, ginger, liquorice, lavender, mint, mustard, olive oil, opium, rhubarb, rosemary, sage, and thyme. The “*De Materia Medica*” may be considered as the first compendium of pharmacy [3, 4].

Galen (129 - 199 AD), the most influential Roman physician, wrote the “*Opera Omnia*”, a collection of 20 volumes in which he expressed his agreement with Hippocrates and Dioscorides [4]. Galen’s approach to therapy involved polypharmacy. He prescribed medicines in simple or complex mixtures called “galenics” which were specifically devised for each therapy. He argued that for each disease, the body would be able to select the appropriate ingredient [3, 4].

After the fall of the Roman Empire, Europe entered the Medieval Age (5th to 15th centuries), and the cultural center was transferred to the East, to the Byzantine Empire and Arab world [3]. The Greco-Latin texts were translated into Arabic, and three important scientific figures emerged during that era.

Abu Bakr al-Razi, known in the West as Rhazes, was born in Iran (865 - 925). He was a physician and a philosopher and wrote about 200 books, including the two main works related to medicine “*Kitab al-Mansuri fi al-tibb*” (“The Book of Medicine for Mansur”) and “*Kitab al-Hawi fi al-tibb*” (“The Comprehensive Book on Medicine”). Rhazes introduced sedative procedures with opium before performing surgery on his patients and also recommended to test the drugs in animals before administering them to humans. Later on, another physician from Persia surpassed his influence, *Abu Ali al-Hussain ibn Abdallah ibn Sina* (Avicenna in Latin) (980 - 1037). Avicenna merged Greek and Arab traditions, further developed Galen’s complex ideas, and described the use and efficacy of 760 drugs

arranged alphabetically in his work “*al-Qanun fi at-tibb*” (“The Canon of Medicine”). In the 12th century this treatise was translated by Gerardo de Cremona into Latin (after the Arabs were driven out of Spain) and was adopted as a standard text for medical students throughout Europe until the 18th century [3, 4]. *Abu al-Qasim Al-Zahrawi* (Abulcasis in Latin) born in Cordoba, wrote the medical encyclopedia “*al-Tasrif*”. Volume 28 describes the correct manner of handling plant products for medicinal application, with an emphasis on the importance of drying and storage techniques. He included more than 1500 herbal drugs, such as liquorice root, opium, aloes, sandalwood, acacia, and cardamom, described the plants and their natural habitats, specified the selection of the plant organs as well as the season in which they should be collected. There is also information about the preparation of oils, vinegars, decoctions and other dosage forms. The work was translated into Latin by Simon of Genoa and printed in Venice in 1471, becoming known as “*Liber Servitoris*”. Many generations of European apothecaries relied on it as a first-hand source of information on pharmaceutical processes [3, 4].

With the development of the printing press by Johann Gutenberg in the mid-15th century, printed herbals and formularies listing drugs and their use became more widely accessible. In 1530, Otto Brunfels (Germany, 1488 - 1534), a Lutheran preacher, published the “*Herbarium Vivae Eicones*”. The most influential herbal writer was Leonhart Fuchs (Germany, 1501 - 1566) whose “*De Historia Stirpium*” was published in 1542. He was a professor of medicine in Tübingen and described in his book more than 500 plants. Subsequently, Hieronymus Bock (1498 - 1554) published in 1546 his “*Kreuterbuch*” in German, in which he includes own observations on plants. Subsequently, Rembert Dodoens (Belgium, 1517 - 1585) wrote “*Cruydeboeck*” (1554) and “*Pemptades*” (1583). Later on, Valerius Cordus (Germany 1515 - 1544) collected the herbs described by Dioscorides in “*De Materia Medica*” and his observations and work were published by the Council of the city of Nuremberg under the name “*Dispensatorium*” in 1546 and 1561. It was edited and published as the herbal “*Historia Plantarum*” by the Swiss naturalist Conrad Gesner. In 1544, the Italian medical botanist Pietro Andrea Gregorio Mattioli (1501-1577) published “*Di Pedacio Dioscoride Anazarbeo Libri Cinque*”, his translation of the work of Dioscorides [4]. Renaissance herbals contain a large collection of plants and combine information from Greek, Roman, and Arabic traditions. They were the predecessors of the pharmacopoeias [8].

In 1498, the first official pharmacopoeia was compiled and printed in Florence by the Guild of Apothecaries and the Medical Society, under the name “*Nuovo Receptario*”. Other cities produced their own pharmacopoeias, including Barcelona and Zaragoza (1535), Nuremberg (1556), Basel (1561), Augsburg (1564), Cologne (1565), and London (1618) [9].

Amid the Renaissance, Philip Theophrastus Bombastus von Hohenheim - he called himself Paracelsus (1493 – 1541) - was born in Einsiedeln (Switzerland). His advanced ideas changed drug therapy, but were regarded as strongly controversial in his time. He used metals such as antimony and mercury to treat his patients. He knew that such substances were toxic, but he realized that the hazardous effects depended on the dose (“*sola dosis facit venenum*”). In this way, Paracelsus became the “Father of toxicology”. He gave also great importance to the way the remedies were prepared. Separation was considered the fundamental process in his chemical philosophy: “what the eyes perceive in herbs or stones or trees is not yet a remedy; the eyes see only the dross. But inside, under the dross, there the remedy lies hidden” [4, 10-12].

The discovery of America in 1492 brought with it the incorporation of new plants used for medicinal purposes in Europe. Ipecacuanha root (*Cephaelis ipecacuanha*) and cinchona bark (*Cinchona ssp.*) were some of the best known [13-16].

- **History of Cinchona Bark**

The origin of the cinchona bark and how it first came to Europe lacks of precise information, and some legends and false statements have sprout around its history [17].

Allegedly, the cinchona bark was introduced in Europe in the early 17th century by Jesuit priests. They were doing missionary work among the new-world indigenous communities. During 1630, the Jesuit apothecary Agostino Salumbrino (1561-1642) learnt that Peruvian indigenous chewed the bark while working in cold airflows in Spanish-owned mines to stop shivering. He reasoned that the bark also might stop the shivering coming from attacks of the ague (British name for malaria¹). The Jesuits brought this information together with the bark to southern Europe, where malaria was a serious problem. The bark became known as the Jesuit’s powder, Peruvian bark, or quina-quina, amongst others [13-16].

Initially, cinchona bark was met with a lot of skepticism due to religious beliefs of that time. Some Protestants in England called it “the powder of the devil”. Additionally, the evidence of efficacy was confusing. On the one hand, a number of European physicians had remarkable success in treating patients with cinchona bark, but there was also numerous failures. They could be attributed to a wide variety of cinchona species, which showed great differences in the active component (quinine) and due to lack of

¹ Malaria is the most important parasitic disease in human beings. It is a protozoan disease transmitted by *Anopheles* mosquitoes. Five species of the genus *Plasmodium* causes malarial infections in humans. The most characteristic symptom is fever that occurs in four-to-eight hour cycles. First, a feeling of coldness with shivering that lasts for up to an hour appears, then a fever that lasts for two to six hours develops, accompanied by severe sweating [23].

authenticity of the herbal samples. Usually, the merchants collected the bark only after the bitter taste [13, 14].

Later, the use of cinchona bark became firmly established throughout Europe thanks to the sustained therapeutic success of practitioners like Sir Robert Talbor (England, 1642 - 1681). The publication of books which favorably advocated cinchona for its antimalarial properties, namely “The English Remedy or Talbor's Wonderful Secret for Curing of Agues and Feavers” in 1686, and “Pyretologia, A Rational Account of the Causes and Cure of the Agues” in 1692, are both attributed to Talbor. Cinchona bark became one of the most valuable commodities shipped from America to Europe [13-17].

In 1741, Carl Linneus (Sweden, 1707-1778) established his system of botanical classification of plants and gave to the genus the name *Cinchona*, in honor of the Countess of Chinchón from Spain. Confusion over Spanish, Latin, and Italian orthography led to the accidental dropping of the first “h” [13, 16, 17].

By the late 18th century, formulations were standardized and prepared in pharmacies, which during this time started to grow to become into pharmaceutical companies. Cinchona was more widely accepted as a treatment for specific intermittent fevers. However, adulteration with other herbs, quality (content of active principles), and availability were still an issue. Several species of cinchona trees became almost extinct. The desire to overcome these problems together with the curiosity regarding biological activity prompted the isolation of the active principles [4, 13, 14, 18, 19].

In 1820, the French pharmacists Pierre Pelletier and Joseph Caventou isolated quinine from *Cinchona cordifolia* [2, 4] by repeating the experiments previously performed by the Portuguese surgeon Bernardino Gomez, who managed to isolate cinchonine in 1811 [4]. Quinine was not only more reliable, but also less bitter than the bark and soon became the norm in the treatment of malaria. Caventou established a factory for the production of quinine in the mid-1820s. This alkaloid became hence the first commercial pure drug substance [2, 13, 14]. The early 19th century became the first days of modern medicinal chemistry in which the focus was laid on the isolation of active principles from plants, mainly of alkaloids such as morphine, emetine, and atropine [2, 18, 19].

There was the need to establish cinchona tree plantations to obtain plant material to isolate quinine. Charles Ledger, an English entrepreneur, discovered together with his servant Manuel Incra Mamani a variety of cinchona species with high quinine content (*C. ledgeriana*). The seeds were sold to the Dutch government in 1865. Within a short time, the Dutch plantations established in Java were producing 97% of the world's supply of bark, in the 1930s about 10 million kilograms of bark per year. From the mid-19th century to the 1940s, quinine was the standard drug for malaria throughout the world [13, 16]. Cinchona

bark is one of the historically most successful herbal remedies and illustrates the value of folk medicine [6].

The total synthesis of quinine was achieved by Robert Woodward and Eggers Doering in 1944. However, the bark still remains the only economically practical source of quinine [13, 15].

By the end of the 19th century, the understanding of organic synthesis and chemical structures led to the structure elucidation and to the synthesis of first derivatives of isolated natural products. The chemical structure of quinine was elucidated in 1908 (Fig. 1) [2, 4, 13]. The course of structure determination in the early days of the natural product chemistry was a complex, indirect process combining evidence from many types of experiments [1].

Figure 1. Chemical Structure of Quinine

The English chemist William Perkins failed in synthesizing quinine, but succeeded in synthesizing “mauveine”, the first synthetic textile dye that did not wash off in water. This sparked the development of a German synthetic dye industry which had a profound influence on organic chemistry and medicine [4, 14, 20]. The German physician Paul Ehrlich (1854 - 1915) discovered the affinity of dyes for biological tissues. Based on these observations he postulated the existence of “chemoreceptors”. Ehrlich later argued that certain chemoreceptors on parasites, microorganisms, and cancer cells would be different from analogous structures and claimed that these differences could be exploited therapeutically. This was the birth of chemotherapy. During his work with dyes, Ehrlich tested the effects of methylene blue on malaria parasites and trypan red on trypanosomes, and he became the first scientist searching for drugs against parasites [16, 20, 21].

Until the mid-20th century, most drug prototypes were derived from plants and once again, the fight against malaria became a good example of drug discovery during this era [4]. In World War I (1914 - 1918), German soldiers suffered from malaria, but Germany could not access quinine sources in Java. Bayer, one of the leading chemistry companies, was therefore commissioned during the 1920s to find a synthetic alternative based on quinine as prototype. Bayer developed plasmoquine (1925), mepacrine

(1932), resochin (1934), and sontochin (1936). The latter was considered as the most effective and toxic compound, and its production was initiated (Fig. 2) [13-15].

Figure 2. Some Antimalarial Derivatives Based on Quinine as a Prototype

In World War II the Allies neither had access to sontochin, since the trade with Germany had stopped, nor to quinine because of the Japanese occupation of Java. Thus, the Allies had to develop new synthetic antimalarials. British, Australian and American scientists synthesized and screened around 16.000 molecules. The most active and less toxic of these compounds was SN-7618. Subsequently, the assessment of its antimalarial properties in both animal models and humans was performed and its utility as a powerful antimalarial demonstrated. The compound was called chloroquine. This compound had previously been discovered and dropped by Germans (this became later on known as the “Resochin error”) [13, 14, 16, 22].

In the 1950s and 1960s the World Health Organization (WHO) started a program for eradicating malaria. Chloroquine was selected as the WHO drug for a wide eradication campaign. In addition, DDT (dichloro-diphenyltrichloroethane) was recommended by the WHO as insecticide against the mosquito *Anopheles ssp.* which transmits the parasite. This action was very successful in areas such as Sri Lanka, where the cases of malaria fell from 3 million in 1946 to 29 cases in 1964. Yet, the resistance of *Plasmodium ssp.* to chloroquine (and *Anopheles ssp.* to DDT) gradually appeared in the 1960s and spread throughout the endemic areas. Therefore, new antimalarial drugs were needed [13, 14, 22, 23].

- **History of Artemisinin**

In 1960s, the government of the People's Republic of China embarked on a systematic examination of traditional remedies as sources for new drugs [7, 23]. One of the examined plants was *qing hao*, *Artemisia annua* L. (sweet worm-wood or annual wormwood), first mentioned in the “*bencao Gangmu*” nearly 2000 years ago and many times subsequently [6, 7, 15, 23].

In 1972, the female Chinese chemist Tu Youyou (1930-) isolated seven sesquiterpene compounds from an ethyl ether extract of *A. annua* obtained at low temperature. One of them, called *qinghaosu* (extract of *qing hao*), was found to bear the principal antimalarial activity. Its Western name is artemisinin [6, 7, 15].

The structure of artemisinin was determined in 1979 (Fig. 3). In the 1970s, there were already a number of physicochemical, spectroscopic, and spectrometric techniques available for structure elucidation. Still at that time, it was a major intellectual achievement. Its structure and absolute configuration was deduced with the aid of techniques as NMR, mass spectrometry, and X-ray diffraction analysis. Artemisinin is a sesquiterpene lactone with an unusual feature in its chemical structure, a 1,2,4-trioxane peroxide group [6, 7, 13].

Figure 3. Chemical Structure of Artemisinin and Some Derivatives

The antimalarial activity of artemisinin *in vitro* was comparable with that of chloroquine. *In vivo* the compound was assessed in rodent, avian, and monkey malarial models with positive antimalarial activity, and total clearance of parasitemia was achieved [13, 23].

The toxicity of artemisinin was found to be low when tested in animal models, and no mutagenic or teratogenic effects were observed [7, 13].

In 1974, large-scale clinical trials started. During the first studies in China, more than 2099 cases of malaria (*P. vivax* and *P. falciparum* in a ratio of about 3:1) were treated with different dosage forms of artemisinin, leading to the clinical cure of all patients. Additionally, 143 cases of chloroquine-resistant falciparum malaria and 141 cases of cerebral malaria were successfully treated [7]. In summary,

artemisinin showed rapid action, low toxicity, and was effective against chloroquine-resistant *P. falciparum* [23].

Today, artemisinin is considered as one of the most potent and effective antimalarial drugs. Although it rapidly suppresses the parasitemia caused by of *P. falciparum* and *P. vivax*, the problems encountered with recrudescence and solubility, led to efforts to improve the natural product by modifying its chemical structure. The essentiality of the endoperoxide group became readily apparent when testing seven other sesquiterpenes isolated from *A. annua* which lacked this particular moiety [7, 24]. Dihydroartemisinin (DHA), which is obtained by reduction of artemisinin, showed better potency [7]. The two main types of DHA derivatives currently used in the treatment of malaria are ethers and esters (Fig. 4). The most active ether is artemether, and the most promising ester derivative is artesunate [7]. In general, artemisinin derivatives are more potent than the parent compound [23]. To avoid resistance and to overcome the recrudescence problem, artemisinin and its derivatives must be used in combination with other antimalarials [7, 13, 15, 25].

The mechanism of action of artemisinin is not fully understood, despite advances in the biology and biochemistry of the *Plasmodium* parasite. It is known that the integrity of the endoperoxide bridge is necessary, but not sufficient on its own, for antimalarial activity. The most likely mode of action is the ion-dependent alkylation of the heme group and the malarial translationally controlled tumour protein (TCTP). Nevertheless, it is clear and remarkable of that artemisinin has an entirely different mode of action than chloroquine [13, 24, 26].

Figure 4. Artemisinin Derivatives

As a result of the clinical and pharmacological research carried out during the last decades, standard therapy for uncomplicated falciparum malaria is an artemisinin derivative in combination with other antimalarial drugs (artemisinin combination therapy, ACT). In the case of severe malaria (caused by *P. falciparum*, *P. knowlesi*, or *P. vivax*), which constitutes a medical emergency, parenteral artesunate is the treatment of choice. ACT plays an important role in any program attempting to control malaria. The major problem today is to find a steady and inexpensive supply of artemisinin [13, 25, 27].

From a developing world perspective, plant-derived artemisinin remains expensive. The price ranges from US\$ 150 to 1600 per Kg of compound. If the drug was made available at an affordable cost, it could be used not only for the treatment of malaria, but also of other parasitic tropical diseases such as schistosomiasis and leishmaniasis, for which artemisinin has also shown promising activity [28]. Even though different synthetic routes have been reported so far, *A. annua* still remains the best source of artemisinin worldwide [6, 7, 15]. The artemisinin content varies between 0.01 and 1% (w/w) of the dry leaves. Consequently, the production of artemisinin is struggling to keep up with the demand. To overcome this shortage, several strategies for the production of the drug have been developed as follow: i) semi-synthesis; ii) plant cell fermentation; iii) heterologous expression of the biosynthetic pathway in yeast or bacteria, frequently with modification of the genes to optimize production; iv) genetically modify *A. annua per se* to increase artemisinin yield by overexpression of the farnesyl diphosphate synthase. Yet these efforts have not resulted in dramatic improvements [7, 15, 29].

The discovery of artemisinin did not only contribute to a structurally novel and well-tolerated class of rapidly acting antimalarial agents, but also encouraged the investigation of folk medicine [7].

The history of malaria chemotherapy is a good example of how natural product-based drug discovery has evolved. The process can be summarized as follows: i) identification of medicinal plants (e.g. *Cinchona* *ssp.* and *Artemisia* *ssp.*) used by indigenous people to treat diseases; ii) early period of random isolation of active principles, and subsequent determination of structure and biological activity (e.g. quinine); iii) further isolation and structure elucidation of compounds (facilitated by the rapid advancement in chromatographic and spectroscopic techniques), semisynthesis of derivatives, and elucidation of biosynthetic pathways in the plants (e.g. artemisinin) [1, 4, 13-15, 18, 19, 30].

2.1.2 Current Drug Discovery Process

The process of drug discovery and development (DDD) requires between 12 – 15 years, 13.5 on average, and an estimated investment of US\$ 1.5 billion for a single new drug [31-33]. Figure 5 provides a summary of the sequential steps that are necessary for a drug to progress through the DDD pipeline [34-36].

The initial phase of DDD is the drug discovery process, which typically involves three main stages: target identification and validation, hit generation, lead generation, and optimization. In the last 20 years, the incorporation of new technologies along these steps has evolved into a “new” concept in drug discovery. [35, 37].

Figure 5. Drug Discovery and Development Pipeline. The figure shows an overview of the DDD course (arrows). Drug discovery comprises the first 3 phases (peach), while the drug development phase consists of the 4 following steps (blue). The rectangles (upper part) describe the objectives and major activities performed during each one of the development phases. The registration step (green) takes place in the different countries or regions where the drug is to be commercialized, i.d. USA (Food and Drug Administration, FDA), Europe (European Medicine Agency, EMA), and Japan (Ministry of Health, Labor, and Welfare of Japan, MHLW). At the bottom: average time span in each phase and required authorizations issued by regulatory agencies along the process. IND (Investigational New Drug application) to conduct clinical trials in the USA, IMP (Investigational Medicinal Product dossier) in Europe. NDA (New Drug Application) to approve a new pharmaceutical product in the USA, MAA (Marketing Authorization Application) in Europe. PK (pharmacokinetics). Adapted from [34, 36, 38, 39].

Identifying and validating disease-modifying targets is an essential early step in the drug discovery pipeline. The development of genomics, proteomics, and mouse gene knock-out models has opened the possibility to find a wide variety of molecular targets [33, 35, 37]. This has represented a major paradigm shift from older drug discovery strategies, which only utilized whole-animal physiology-based testings [33]. The target validation consists of confirmation of the role of the target prior to passing into the following drug discovery pipeline. It is accomplished by using either cellular or animal models for modulation of gene expression and/or protein function [40].

The next step is to perform a screening to find hits. A hit is an active compound which exceeds a certain activity threshold in a given assay [31, 41-43]. Currently there are several hit discovery techniques. Since approximately two decades one of the most commonly used approach is the high throughput screening (HTS). In the automated and miniaturized HTS formats, a large number of biochemical and cellular targets are exposed to a great number of small molecules [43].

The small molecules which should be tested can be derived from many sources. Theoretically the optimal strategy would be to screen as many molecules as possible. However, it is the resources required that indicate the optimal size of the compound collection. Therefore, assessing the chemical space and diversity of compound collections are essential components of the solution of this problem [32, 43].

Among this “new” drug discovery concept (HTS capability combined with a great number of molecular targets), it is possible to carry out a whole screening program within short time (typically around 3 months). This new approach is potentiated with the capability to synthesize a great number of new molecules through combinatorial chemistry, parallel synthesis, and other techniques. Consequently, a considerable amount of “hits” can be identified [19, 37, 41, 44-46]. Yet, the identified hits must be validated by demonstrating a desirable response in different biochemical and cellular assays [32, 43].

Once the hit has been validated, the hit-to-lead process starts. Not all biologically active compounds (hits) have the desired properties to become a drug. An optimized lead is a molecule with a good balance between potency, favorable pharmacokinetics (PK) properties, and a good safety profile. Hence, during the hit-to-lead process, strategies such as bioisosteric replacement are applied to synthesize series of compounds with well established structure-activity relationship (SAR), wherein compounds with similar structures exhibit similar target binding affinities but with varying PK properties and safety profiles. Potency, PK, and safety of synthesized compounds are assessed in a set of *in silico*, *in vitro*, and *in vivo* tests which guide the compound selection [31, 35, 43, 47, 48].

Within the drug discovery process and particularly in the PK process where ADME (absorption, distribution, metabolism, and excretion) properties are assessed, the concept of drug-likeness is a key tool. This concept is associated with properties defined by Lipinski's "rule of five". Nineteen percent of the orally available drugs have fewer than 5 hydrogen-bond donors (expressed as the sum of OHs and NHs), less than 10 hydrogen-bond acceptors (expressed as the sum of Ns and Os), molecular masses of less than 500 Da, and logP values (a measurement of lipophilicity) of less than 5. Computational calculations predict "rule of five" properties for prospective compounds [31, 32, 41, 47, 49].

Figure 6 illustrates the optimization process from hit-to-lead of an imidazolepiperazine intended to be administered orally as antimalarial. After the lead optimization, the DDD course continues to the pre-clinical and further development phases (Fig. 5).

Figure 6. Optimization of an HTS Hit to Lead for an Orally Active Antimalarial. In this example the Novartis natural products (NP) and natural product-like synthetic compounds library was screened. Compound **11**, an imidazolepiperazine, was chosen as a hit due to its potency *in vitro* against *P. falciparum* and its favorable physicochemical and ADME properties. However, the compound showed some toxicity issues (hERG binding). After early optimization, a lead compound (**12**) was selected. Its *in vitro* potency, PK, and *in vivo* efficacy were improved in comparison to the hit, but the hERG binding was still a problem. After understanding the SAR of hERG binding and differentiation from potency, both safety and potency of the lead could be improved alongside with its PK (the substitution of the benzylic carbon of the piperazine was a key point). As a result, an optimized lead compound was obtained (**13**) [50].

So far, the above described “new” concept of drug discovery has not been as productive as expected. Only very few leads and developed compounds can be attributed to the new drug discovery paradigm. From 2003 to 2009, a total of 12 compounds originated from HTS hits were introduced into the pharmaceutical market [19, 32, 41, 44-46].

- **Natural Products (NPs) and Their Role in Current Drug Discovery**

There is no doubt that NPs have been historically very valuable in the drug discovery process and that they still constitute a successful source for new drugs [1, 30, 41, 44, 46, 48, 51].

According to Newman and Cragg, a total of 1355 new chemical entities (NCEs) were approved between 1981 and 2010, including vaccines, biologicals, and “small molecules” [52]. In these 30 years, NPs were the source of 35% of all small molecules ranging from 12% in 1997 to 50% in 2010 [52-54].

Moreover, many semi-synthetic NPs analogs or synthetic compounds based on NPs pharmacophores have been obtained. Particularly, about 38 NPs-based drugs, 10 NPs, 15 semi-synthetic compounds, 12 NPs derivatives, and 1 synthetic congener were approved and launched in the market between 2000 and 2010. Fifteen were intended to treat infectious diseases, 7 to treat cancer, 7 against neurological disorders, 4 against metabolic and cardiovascular ailments, 1 to treat diabetes, and 4 intended for other areas (inflammation, immunomodulation, pain, etc.) [52-55].

Challenges

Despite of the NPs success, many large pharmaceutical companies have reduced and cut down the use of natural products in the drug discovery programs. The reasons for this decreased interest range from commercial to scientific, but one of the main explanations is that NPs are not amenable to the aggressive timelines of the HTS [30, 41, 44-46, 56, 57].

Additionally, NPs sources have some disadvantages compared to synthetic libraries concerning their incorporation into HTS programs: i) NPs show a higher number of false-positive results in the assays, due to the presence of compounds with non-specific activities, or interference with the assay read-out; ii) repeated isolation of the same compounds is challenging; iii) NPs may contain only very small quantities of a bioactive substance, often as a mixture with structurally related molecules, which requires labor-intensive and time-consuming purification procedures; sometimes the concentration of these small quantities of bioactive substances may even be too low to be effectively detected; iv) NPs are often structurally complex (a lot of functional groups and chiral centers); these factors delay the identification process and contribute to problems of supply and manufacture; v) increasing complications arise in the

handling of intellectual property and in the access of bio-materials as a result of the Rio Convention on Biological Diversity in 1992; vi) seasonal or environmental variations in the composition of living organisms can cause problems with initial detection of active compounds as well as subsequent repetition of assays or purification; the loss of source is also possible (extinction) and vii) NPs discovery has been perceived as old-fashioned compared to emerging technologies [30, 41, 44-46, 52, 58].

Opportunities

The pharmaceutical industry is currently facing high economic pressure due to product recalls, aggressive generic competition, and the looming patent cliff. Due to the lack of productivity of the “new” drug discovery concept, there is a steady decreased number of NCEs launched into the market. For instance, the number of small molecules introduced per year between 1981 and 1989 was 50, in the next decade the number lessened to 40, and between 2001 and 2010 it was around 20 (with the exception of the years 2002- 2005, when the figures climbed above 30). Moreover, not only less NCEs have been introduced in the market, but more money has been invested in discovery and development. As a result, the costs of bring a drug to market has increased [30, 33, 45, 52, 57, 59-61].

Owing to these factors, the industry has refocused efforts on strategies that are most likely to yield sustainable products. A critical part of this refocusing includes the re-evaluation of drug discovery processes. This is where the NPs may play an important role again in generating novel and structurally unique scaffolds [30, 41, 44-46, 61].

There is a number of characteristics that make NPs structures “privileged” to elicit a biological activity: i) higher chemical diversity and complexity. Even though, this is considered as an incompatibility factor with an HTS program, this is one of the noteworthy characteristics for both finding active compounds and new mechanisms of action; ii) biochemical specificity. NPs are produced by biosynthesis in living organisms as a result of evolutionary pressures to interact with a wide variety of proteins and other biological targets. This means that NPs have an imprint of biological space (protein fold topology) and preferentially bind to these folds. The fold space is the total repertoire of three-dimensional protein structures; iii) drug-like properties. NPs show compliance with Lipinski’s type descriptors in approximately 90% [41, 45, 46, 51, 57, 58].

In addition to the privileged structure of NPs, still much of the nature remains to be explored as source of novel active agents [52]. For instance, fewer than 1% of microbial species are culturable, and fewer than 12% of higher plants species have been examined for bioactivity [62]. Certain insects and other animals have been targeted for specific bioactivities, such as toxins, but are not generally subjected to

HTS efforts. Clearly, the biological resource is there, but access and examination is problematic, especially if there is pressure because of a short time frame for discovery of new compounds [57].

However, this renewed interest on NPs can only be sustained if NPs research can be competitive with other drug discovery techniques. Key factors to achieve this competitiveness include uninterrupted technological improvements in the NPs-based lead discovery, such as speed of dereplication, isolation, structure elucidation, and compound supply processes. Some of these approaches will be discussed in the next subchapter [30, 45].

2.1.3 Current State of NP Discovery

In the classical approach for NPs isolation, the process of “bioassay-guided fractionation” starts when a extract, obtained from terrestrial plants, marine organisms, microorganisms, and/or animals, shows a positive response in a screening. Then, it is necessary to isolate the pharmacologically active pure constituent from the total extract. However, extracts are complex matrices that require a long process, substantial material amount and financial resources [1, 42].

The original crude material (large amounts) is split into fractions which are tested in biological assays to track the active compounds. Typically, liquid-liquid partitioning between immiscible phases and consecutive chromatographic separations in open column chromatography (normal phase) are performed. Subsequent steps are generally of higher resolution by using RP-HPLC. The separation performance in these initial fractionation steps is poor and very often the activity is lost in the course of the isolation. Furthermore, the compounds’ structures are disclosed only at the end of the whole elaborated and resource-consuming process. This can turn out in disappointment if the isolated compounds are already known structure. Therefore, the approach described above does not match the timelines and the workflow of modern drug discovery [30, 42, 58].

However, technological advances in instrumentation, robotics, and bioassay miniaturization have increased the speed of bioassay-guided isolation and structure elucidation of NPs considerably, and these improvements have allowed NPs research to be more competitive with synthetic compounds screening and HTS. Some of the most important advances in this field are discussed below [30, 45].

- **Libraries**

Ideally, NPs screening libraries would consist of pure compounds in order to obviate confounding responses derived from mixtures, and to avoid the lag time required to deconvolute a mixture for the identification of the active component [61]. Libraries of pure compounds, present in known amounts, are screen-friendly and accommodate the desire for short timelines in examination of a large number of molecules. These libraries combine one of the strengths of HTS with the concept of chemical diversity [32, 57].

Additionally, with a NPs compound library it is possible to create a target-oriented or focused-library approach which seeks to elaborate structural modifications onto an existing bioactive NP scaffold in a parallel, systematic fashion to improve the compound’s inherent biological activity or drug-like properties. This can be performed either by semi-synthetic modification of the parent molecules, or by fully synthetic methods [41, 45].

However, assembling a highly diverse library of NPs for screening is a major endeavor because, the commercial availability of pure NPs remains quite limited. An alternative can be pre-fractionated NPs libraries, which combine the benefits of incorporating much greater chemical diversity with reasonable consistent biological readouts. Simplified mixtures resulting from pre-fractionation expedite the downstream processes of dereplication and of compound purification and therefore reduce the lag time. Pre-fractionation schemes aim to include the bulk of constituents, rather than only including major components or “peaks” hence the opportunity to discover novel compounds is preserved [30, 42, 61]. Some approaches go beyond and propose to create libraries of initial optimized extracts to lead-like and drug-like space with a particular emphasis on logP, one of the most important physicochemical parameters, followed by fractionation to afford a HTS-friendly NP screening library [51].

- **High performance liquid chromatography (HPLC)**

High performance liquid chromatography (HPLC) is one of the most powerful tools in chemistry, with the ability to separate, identify, and quantitate the compounds present in any sample that can be dissolved in a liquid. HPLC can separate water-soluble, thermally-labile, non-volatile compounds with speed, precision, and high resolution. HPLC is used routinely in phytochemistry both in analytical and preparative scale [63].

In recent years, a wide variety of stationary and mobile phases have been developed to give a large potential of different kinds of separations. Most common used stationary phases are reverse phase (RP), based on octadecyl (RP-18) and octyl (RP-8) materials with particle diameter around 5 μm . Current reverse-phases are highly selective, offer high separation power, robustness, stability, and efficiency. The introduction of spherical particles has led to a reduction in the size of the particles and the length of the columns, from 25 cm (8000-10000 plates/m) to around 10 cm, with the same number of plates/m. In ultra high-performance liquid chromatography (UHPLC), particle sizes of around 1.7 μm are used. Other modified phases such as cyano, phenyl, trimethylsilane, triazole, secondary and tertiary amines are available. Typically, the mobile phases are combinations of water and either methanol or acetonitrile [63, 64].

When HPLC is applied to analytical work, the goal is to get information about the sample. The most important parameters are resolution, sensitivity and fast analysis time. In preparative HPLC, larger columns and larger quantities of packing materials are needed. The aim here is to isolate and/or purify compounds, and the most important parameters in this kind of chromatography are the degree of solute purity, the throughput, measured as the amount of compound produced per unit time, and the load capacity [63].

The potential of HPLC has been boosted by coupling the LC part with different detectors such as UV/DAD (HPLC-UV), MS (HPLC-MS), MS/MS (HPLC-MS/MS), ELSD (HPLC-ELSD), NMR (HPLC-NMR) and circular dichroism (CD) (HPLC-CD). This hyphenation of HPLC with spectroscopic methods has led to new strategies that permit i) to authenticate botanical samples by creating fingerprints; ii) to obtain complete spectroscopic characterization of present compounds to differentiate between known and unknown compounds; iii) to determine the structure of unknown plant metabolites directly without previous isolation and minimum amounts of material iv) to establish the absolute configuration of the new compounds by measuring their CD spectra. Most of these applications are useful in analytical work, but also for preparative separations, the introduction of HPLC-MS has enhanced the range of application [58, 63-65].

- **LC-MS**

Mass spectrometry is one of the most sensitive analytical methods which provides information about the structure of analytes and about their molecular weight. This technique has had a dramatic and rapid advance in recent years. An LC-MS system includes the HPLC system, the ionization source (which interfaces the LC to the MS), and the mass spectrometer [1, 63, 66].

Their most common ionization sources are electrospray ionization (ESI) and atmospheric pressure chemical ionization (APCI). Both ESI and APCI ionization occurs at atmospheric pressure, hence these sources are referred to as atmospheric pressure ionization (API) sources. In ESI, the high voltage field (3-5 kV) causes about nebulization of the column eluents resulting in charged droplets that are directed toward the mass analyzer. Ions are then released from the charged droplets by direct ion emission (a process called “ion-evaporation”), and are finally separated according to their mass/charge ratio in the mass spectrometer. In APCI, heat is applied to vaporize the column eluents, and then a corona discharge ionizes the solvent molecules, which results in the formation of analyte ions via chemical ionization [63, 66].

The most frequently used mass spectrometer for HPLC-MS is the single quadrupole, which provides a mass spectrum for each chromatographic peak that elutes from the LC column. Another type of spectrometer used in NPs research is the time-of-flight (TOF), which provides a high resolution spectrum for each analyzed component [66].

- **Dereplication**

Dereplication is the process of identifying known compounds that are responsible for the activity of an extract before bioassay-guided isolation begins. This process is used to eliminate, group, and/or prioritize

extracts for further studies, and it can save considerable research time. The chemical and biological characteristics of the unknown compounds are compared with the chemical and biological characteristics of known compounds from the data-bases to eliminate those that have been isolated previously [41, 45, 46, 58, 67].

The procedure involves separation of an extract using RP-HPLC and splitting of the eluent post column into a fraction collector using microtiter plates and in a mass spectrometer for analytical purposes. The collected fractions in the microtiter plates are dried, redissolved in an appropriate solvent, typically DMSO, and assayed. The retention times, UV spectra, MS data, and activity of the fractions are analysed, and commercial and in-house databases are used for comparison. Databases such as the Dictionary of Natural Products contain chemotaxonomic, pharmacological, and molecular weight information. This approach constitutes an off-line HPLC-based activity profiling. Other setups are fully integrated on-line approaches, where HPLC fractionation is coupled directly to biochemical assays, such as on-flow post-column bioassays and at-line settings. However, the off-line format is highly versatile because it can be applied to different kinds of bioassays after adaption of the fractionation protocol to the required sensitivity of the assay [30, 45, 58]. Some examples of the off-line approach include the HPLC-based activity profiling for the identification of NPs with GABA_A receptor modulating activities [68] and for NPs with antiprotozoal activities [69]. The off-line approach has been used with numerous other targets, such as, for inhibitors of the DYRK1A kinase, a target implicated in neurodegenerative diseases [70], or for anti-HIV inhibitors [71].

Tracking bioactivity in extracts, which are complex matrices, remains a highly challenging task. But HPLC-based activity profiling allow not only to dereplicate known active compounds, but also to carry out a target preparative isolation of the active principles present in the active fraction [58, 67].

- **Structure Elucidation**

With the advances in X-ray crystallographic, NMR, chiroptical, and mass spectrometric techniques, structure determinations for NPs has become quite routine [1, 72].

NMR

Introduction of nuclear magnetic resonance (NMR) spectroscopy into organic chemistry has changed the way of structure determination. Fifty years ago, NPs structure elucidation was an extremely difficult and lengthy task which required carrying out several synthetic steps and degradation reactions. The thereby obtained data was combined to eventually allow the determination of the structure. However, even total chemical synthesis of compounds of interest was needed to corroborate the proposed structures. By the

1950s, the development of commercial IR and UV/VIS spectrometers allowed NPs chemists to use these techniques for functional group characterization. Following the discovery of the NMR phenomenon, its potential was early recognized and its application for the identification of organic compounds started. In 1950, NMR spectrometers required a skilled operator. However, with the introduction of user-friendly NMR spectrometers since the 1960s, the potential of this technique has become more accessible for the scientific community and over the time, the improvements in the commercial instrumentation have revolutionized NPs structure elucidation [1, 72, 73].

The NMR sensitivity has considerably improved. In 1960, a signal to noise (S/N) ratio of 10:1 on a 1.0% sample was obtained. With today's spectrometers, the S/N ratio is 10.000:1 on a 0.1% sample prepared in the same solvent. This improvement was achieved by the introduction of: i) higher field spectrometers using superconducting solenoids; ii) progress in pulsed-field gradients (PEGs). Sensitivity itself is not the only determinant for spectral quality, the level of noise is another important factor. Any instability of the NMR system, fluctuations of the field-frequency-regulation circuit (the "lock") and fluctuations in room temperature or magnetic disturbances may introduce noise. When PEGs are used in experiments, only the desired coherences enter into the receiver, and the effects of short-term fluctuations interfere in a lesser extent; iii) probeheads with superior sensitivity. Cryogenically cooled probes (so-called "cryoprobes"): upon cooling the radio-frequency coil to a temperature of ca. 20 K, thermal noise is dramatically lowered, resulting in S/N ratios generally 3 or 4 times higher than for a conventional probe heads. All these advances provide sufficient sensitivity to record full sets of 2D data within a few hours and with sub-milligrams amounts of sample [72, 73].

Other important improvements were the introduction of Fourier-transformation, allowing more rapid acquisition of spectra and the development of multiple pulse sequences. Two-dimensional (2D) pulse sequences used for structure elucidation, including COSY (^1H - ^1H correlation), HETCOR (1-bond ^1H - ^{13}C correlations), and NOESY (^1H - ^1H nuclear Overhauser enhancement spectroscopy), among others.

Another technological improvement for the application of NMR to NPs analysis is the hyphenation with HPLC. The objective is to create an interface able to deliver the HPLC fractions/pure compounds to the NMR coil. Flow NMR methods has been developed for this purpose. The HPLC fraction is transferred via capillaries into a flow NMR probe. A modification of this technique is the so-called "stopped-flow NMR", and the "loop storage". All these flow NMR methods have two main drawbacks. Firstly, due to the significantly lower sensitivity of NMR compared to MS, it is possible to obtain only a ^1H NMR spectrum in the limited time that the sample is present in the coil region of the flow cell. Secondly, deuterated solvents have to be used or alternative, multiple solvent peak suppression must be carried out.

The most successful approach, so far implemented, is the use of solid phase extraction (SPE) cartridges in combination with LC. By establishing such procedures, multiple injections can be done to build up amounts of isolated samples and the problem with the solvents is eliminated by evaporating the protonated solvents from the cartridges and eluting off the cartridges with deuterated solvents [72, 73].

The most widely used strategy, to determine the skeletal structures of NPs is combining ^1H - ^1H correlations spectra (COSY or TOCSY) with one-bond ^{13}C - ^1H correlations (HSQC and HMBC) to attach together the fragments. However, the actual pulse sequences used to obtain the data have been improved significantly, and additional methods to supplement these techniques has been developed [72, 73]. Previous determination of the molecular formula is very important to support the information deduced from the NMR analysis. Once the skeletal structure of the compound has been determined, the three-dimensional structure must be established. Again NMR information can be useful for doing this. The vicinal ^1H - ^1H and germinal and vicinal ^{13}C - ^1H coupling constants can be used to determine the dihedral angle, alongside with the 2D NOESY and/or ROESY, which constitute powerful methods for indentifying pairs of protons which are spatially close, even if separated by a large number of bonds [72, 73]. However, to assign the absolute configuration (AC) in an unequivocal way, chiroptical, X-ray crystallographic, enzymatic or chiral derivatization methods must be applied [74].

Absolute Configuration

Most NPs and biologically active compounds are chiral and their biological functions are related to their chirality, i.e. their AC. Therefore, the determination of the AC of chiral compounds is critical for the studies of NPs. One of the most sensitive and versatile methods for this purpose is electronic circular dichroism (ECD) spectroscopy, because two enantiomers are unambiguously characterized by their fully opposite CD spectra. In the case of NPs, ECD is the most common approach for AC determination and nowadays, it is even possible to apply hyphenation of CD measurements with HPLC techniques. From the CD spectra, whether taken online or offline, the AC of the respective stereoisomer can easily be determined by i) comparison of the CD spectrum with experimental data from structurally related compounds of known absolute configuration; ii) if the structure fits into semiempirical CD rules, e.g., the octant rule; iii) for novel-type structures, the most efficient alternative for the interpretation of CD spectra is the quantum chemical calculation simulation of the curve for both enantiomers, and their comparison with the experimental ones [65, 75].

2.2 Drug Discovery for Neglected Tropical Diseases (NTD)

2.2.1 Neglected Tropical Diseases

Today, there are 17 parasitic and bacterial infections classified by the WHO as neglected tropical diseases (NTD). These diseases are a substantial health and economic burden in Africa, Asia, and Latin America and cause about 534000 deaths every year. Among them we have Chagas disease, human African Trypanosomiasis (HAT), and leishmaniasis. NTD share common features such as: i) they constitute a proxy for poverty and disadvantage, ii) they affect populations with low visibility and little political voice, iii) their distribution is restricted to the tropics due to allocation of the vectors and their reservoirs, iv) they cause disfigurement and disability leading to social discrimination, v) they can be controlled, prevented, and potentially eliminated by using appropriate chemotherapy and preventive actions such as vector control, good hygiene practices, and personal preventive measures [1, 2].

Malaria was once considered as a NTD, but since 2000, a lot of progress has been made in fighting the disease. In doing so, a reduction of about 45% in mortality rates could be achieved. However, the political commitment and international community awareness must be sustained to avoid losing the progress so far obtained. The burden of malaria is still devastating and the need for drug discovery and development of new antimalarial drugs is urgent [3-7]. In the context of the present work, malaria will be addressed among the NTD. General information about the above mentioned NTD is shown in Table 1.

- **Malaria**

Malaria has caused greater suffering and mortality over the course of human history than perhaps any other disease. Nowadays, malaria is still the most important parasitic disease of humankind. In 2012, there was an estimated of 62700 deaths, mostly of children under 5 years of age in Africa. This implies that 1300 young lives are lost to malaria every day [3, 8].

The life cycle of *Plasmodium* parasites has two stages. The asexual stage develops in humans (or in tetrapod vertebrates, such as mammals, birds, reptiles), and the sexual stage evolves (or develops) in mosquito vectors (*Anopheles spp.*). The mosquito inoculates sporozoites into the human body, while having a blood meal. Sporozoites are motile cells that target the human liver and invade hepatocytes, where they proliferate quickly [8].

After about one week, the developed schizonts burst in the liver, and thousands of merozoites are released into the human blood stream. The merozoites invade red blood cells, and the asexual reproduction begins. The intraerythrocytic cycle has three stages, ring, trophozoite, and schizont. Some parasites develop into gametocytes (the sexual forms), which can be transmitted back to anopheline mosquitos, where the sexual

reproduction starts. Firstly, an ookinete is formed, which develops into an oocyst and finally evolves into sporozoites [4, 8].

Table 1. Neglected Tropical Diseases [1, 8-13]

	Malaria	HAT	Chagas disease	Leishmaniasis
Causative agent	<i>Plasmodium falciparum, vivax, malarie, ovale, and knowlesi</i>	<i>Trypanosoma brucei rhodesiense, T. b. gambiense</i>	<i>Trypanosoma cruzi</i>	<i>Leishmania spp.</i> (~21 species)
Vector	<i>Anopheles spp.</i>	<i>Glossina spp.</i> (tsetse fly)	<i>Triatomine spp.</i> <i>Triatoma spp.</i> <i>Panstrongylus spp</i> (Kissing bug)	<i>Phlebotomus spp.</i> <i>Lutzomyia spp.</i> (sandflies)
Geographic distribution	World-wide	Sub-saharan Africa (countries ~21)	South and Central America (18 countries)	South and Central America, Europe, Africa, Asia (88 endemic countries)
DALYs	55 413.529	1 345.594	499067	3 754.202
Deaths in 2011	589218	19026	7356	53675
Estimated cases	219 million cases	50000-70000 cases	7-8 million people infected	30000 cases of visceral form/ 5 million cases in total

DALYs: Disability-adjusted life years

In endemic areas, malaria is often the most common cause of fever. The first symptoms of malaria are nonspecific, and include a vague absence of wellbeing, headache, fatigue, and abdominal discomfort, among others. Most patients with uncomplicated malaria have fever, mild anemia, and after several days a palpable spleen. Manifestations of severe falciparum malaria are anemia, hypoglycemia, acute pulmonary edema, acute kidney injury, coma in the case of cerebral malaria, and acidosis [8].

Malaria was mainly treated with chloroquine until the 1960s (Fig. 2). But resistance of the parasites to this drug appeared and spread around the world. Currently, sodium artesunate (Fig. 4) is the treatment of choice for severe malaria worldwide (including *falciparum*, *vivax*, and *knowlesi* malaria), due to its effectiveness against cerebral malaria. In uncomplicated *falciparum* malaria cases, artemisinin combination treatment (ACT) (artemether-lumefantrine, artesunate-mefloquine, and dihydroartemisinin-piperaquine) is the recommended first-line therapy in all endemic areas. This therapy is also highly effective against other human malarias. In the chloroquine-sensitive strains of *P. vivax*, *P. malariae*, *P.*

ovale, and *P. knowlesi*, chloroquine is still being used. But emerging resistance to ACT can make malaria resurge [14].

- **Human African Trypanosomiasis (HAT)/ sleeping sickness**

Human African Trypanosomiasis (HAT) is caused by the protozoa *Trypanosoma spp.* The life cycle of African trypanosomes begins in the disease vectors, which are the tsetse flies (*Glossina spp.*) and various mammals. HAT exists in two forms, depending on the subspecies of *Trypanosoma* involved. *T. b. gambiense* infection is characterized by a chronic progressive course of around 3 years and is endemic in 24 countries of western and central Africa. This infection is responsible for more than 98% of reported cases of HAT. In contrast, *T. b. rhodesiense* causes an acute form of the disease, and death can occur within weeks or months. This type of HAT is endemic in 13 countries of eastern and southern Africa and represents less than 2% of the cases. HAT is characterized by two stages. In the first stage, the parasites are in the blood and produce symptoms such as intermittent fever, headache, and pruritus. In the second stage, parasites are able to cross the blood-brain barrier (BBB), which causes clinical manifestations such as sleep disturbances and neuro-psychiatric disorders [1, 9, 15-17].

Currently there are five drugs used for the treatment of HAT, namely pentamidine, suramin, melarsoprol, nifurtimox, and eflornithine (Fig. 7). Pentamidine and suramin are used to treat first stage HAT caused by *T. b. gambiense* and *T. b. rhodesiense*, respectively. Eflornithine and melarsoprol are applied in the second stage of the disease. Regrettably, all used drugs show problems such as (i) lack of oral bioavailability (all compounds must be administered by parenteral route) and lack of chemical stability (suramin rapidly decomposes in air), (ii) complicated and long dose regimens (suramin administration can last up to 30 days) and short half-life (four infusions of eflornithine per day are necessary), and (iii) deadly adverse drug reactions (pentamidine is nephrotoxic, melarsoprol causes a fatal encephalopathy in 10% of the treated patients) [15, 18, 19]. In 2009, a new combination therapy including nifurtimox and eflornithine was released into the market for second stage treatment of HAT caused by *T. b. gambiense*. This treatment shows large advantages over the eflornithine monotherapy since it is easier to administer, reduces the amount of drug required to reach therapeutic effects and requires a significantly shorter hospital stay [13, 17, 19, 20].

- **Chagas disease (American trypanosomiasis)**

Chagas disease is a life-long infection caused by the protozoa parasite *Trypanosoma cruzi*. This pathogen was first described in 1909 by Carlos Chagas and has a life cycle with four developmental stages, two of them (epimastigotes and trypomastigotes) in the vector (kissing bug), and two of them in mammalian

hosts (amastigotes and bloodstream trypomastigotes). The kissing bug transmits the parasites to mammals, where the host cells are located in the heart, gut, CNS, smooth muscle, and adipose tissue. Clinically the disease is characterized by three phases: acute phase (4-8 weeks), indeterminate phase (10-20 years), and chronic phase. The severity of the disease depends on the parasite load, strain, and on patient immune responses. An estimated 30% of infected individuals develop the chronic form, which may be cardiac (arrhythmias, congestive heart failure, cardiac enlargement, thromboembolism, and sudden cardiac death), digestive (enlargement of esophagus and colon), or combined cardiac and digestive, which affects up to 10% of patients [1, 10].

Only two drugs are available for the therapeutic use against *T. cruzi* in humans: nifurtimox and benznidazole (Fig. 7). Both compounds are nitroheterocycles and act as prodrugs. The nitro group is responsible for the toxicity in the parasite, most likely via DNA damage [10]. Both drugs show variable efficacy in different *T. cruzi* strains and cause various side effects which result in treatment discontinuation. In general, benznidazole is the first-choice treatment because it is better tolerated. However, treatment failures are frequently reported [1, 10, 13, 21].

- **Leishmaniasis**

There are more than 21 species of *Leishmania spp.* The parasites' life cycle includes different stages and hosts. The promastigotes are present in sandflies (vector), the amastigotes are present in mammalian macrophages. There are three different types of manifestations of the disease: i) The cutaneous leishmaniasis (CL) is the most common form. Parasites are restricted to the skin and cause ulcers on the face, arms, and legs, which leads to disability and permanently disfiguring scars; ii) the mucocutaneous leishmaniasis (ML) is the most disfiguring form because the parasites destroy the soft tissues of nose, mouth, and throat; iii) the visceral leishmaniasis (VL), also called kala azar, is a systemic and the most severe form. If left untreated, the disease is fatal within 2 years. VL causes fever, weight loss, swelling of the spleen and liver, and pancytopenia. Additionally, some cases of VL may evolve to CL.

Pentavalent antimonials, sodium stibogluconate, and meglumine antimoniate have been used to treat the disease. But resistance has appeared in India, the treatments are long (28 days), and parenteral administration is required. In India, the first line of treatment of VL is amphotericin B. A recently developed liposomal formulation of amphotericin B (AmBisome®) is highly effective, but very expensive. Paromomycin (aminoglycoside) is also effective against VL and VC and shows less adverse effects than amphotericin B. Miltefosine, the first oral treatment of VL, has markedly improved leishmaniasis chemotherapy, but its use is limited due to teratogenicity and high costs (Fig. 7) [1, 9, 10, 13, 19].

Figure 7. Drugs Currently Used for Treatment of HAT (A), Chagas Disease (B), and Leishmaniasis (C)

Available drugs for the treatment of NTD (Fig. 2, 4, and 7) are far from optimal, have shortcomings such as limited efficacy, severe side effects, poor patient compliance, and/or resistance [10, 22, 23]. Accordingly, new drugs are urgently needed. In general, requirements for an ideal drug intended to treat NTD are: sufficient effectiveness, safety, oral administration, short-course treatments, low-costs, stability of the drug in climatic zone IV for at least 3 years, suitability of the drug for children and for pregnant women. There are specific requirements depending on the disease such as activity against the different stages of the disease (HAT) or against a particular species (*P. vivax*) [4, 9, 13, 22, 24-26].

2.2.2 Drug Discovery for NTD

Drug discovery and development for parasitic diseases has little commercial incentives for the pharmaceutical industry. Sales are limited by the short duration of the treatment with antiparasitics compared to other drugs, which are consumed daily for prolonged periods (e.g. cholesterol-lowering and antihypertensive drugs). Nonetheless, development costs are similar for both antiparasitic and “long-term” drugs. Additionally, NTD are prevalent in the developing world and affect low-income people. Thus the deficit of new drugs entering development stage for tropical diseases results mainly from the gap between basic scientific research (early drug discovery), which is usually publicly funded, and clinical development, which is funded by pharmaceutical companies [1, 24, 27].

After this problem had been identified at the beginning of the last decade, a new collaborative mindset was created to produce a sustainable pipeline of new drug candidates to enter development. A new model for drug discovery based on networks and public-private partnerships was implemented. In this context, researchers, institutes, and pharmaceutical industry work in a coordinated effort using open innovation approach to discover and develop drugs to treat tropical neglected diseases. A number of non-profit organizations such as the Bill and Melinda Gates Foundation have supported this initiative. Examples of public-private partnerships and networks are “Medicines for Malaria Venture” (MMV) and “Drugs for Neglected Diseases initiative” (DNDi). Overall, the objective was to create a sustainable and scalable model of drug innovation for NTD with a collaborative work of industry, governments, and non-profit organizations. As a result of those joint efforts, it has been a renaissance of DDD in NTD during the last decade. Nevertheless, there are still major gaps and so far, these initiatives have brought to market only new formulations and combinations of already existing drugs. However, there is a series of compounds in the drug discovery pipeline [5, 7, 13, 23, 24, 28-30].

- **Compounds in Drug Discovery and Development Pipeline Against NTD**

Current projects of DNDi and MMV are listed in Table 2 and are shortly commented.

BCX4945

Plasmodium parasites are purine auxotrophs and require preformed purine bases for the synthesis of nucleotides, cofactors, and nucleic acids. Purine salvage in *P. falciparum* uses hypoxanthine, which is converted into inosine monophosphate, a precursor for all required purines. The purine nucleoside phosphorylase (PNP) is essential for the formation of hypoxanthine, making PNP a target for the purine salvage pathway. Blocking PNP kills parasites by purine starvation. BCX4945 (Fig. 8) causes depletion of hypoxanthine from *Aotus* blood (monkey model of falciparum malaria), demonstrating inhibition of

both hPNP and PfPNP *in vivo*. The efficacy, oral availability, chemical stability, unique mechanism of action, and low toxicity of BCX4945 demonstrate a potential for the development of combination therapies [31]. Currently this compound is undergoing preclinical studies [29].

Table 2. Some Projects of the Global Portafolio of DDD and MMV Pipeline [13, 32, 33]

Disease	Drug discovery	Development				Implementation
		Pre-clinical	Phase I	Phase IIa	Phase IIb/III	
Malaria	Oxaboroles Imidazol	BCX4945 SAR116242 PA1103/SAR116242	DHODH	OZ-439	OZ-277	Artesunate-amodiaquine
HAT	Nitroimidazole Oxaborole		SCYX-7158 (Oxaborale)		Fexinidazole	Nifurtimox-Elfornithine
Chagas	Nitroimidazole	Fenarimol series K777	Tak-187	Azoles (E1224)		Benznidazole Pediatric
Leishmania	Nitroimidazole	VL-2098 Fenarimol series		Fexinidazole (VL) Anfoleish (CL)		Sodium stibogluconate & paramomycin

OZ-277 and OZ-439

Artemisinin and its semi-synthetic derivatives are sesquiterpene lactones which bear an endoperoxide bridge. It is thought that the endoperoxide opens by reduction to alkylate the heme. However, artemisinin has a very short half-life. As a result, new fully synthetic peroxides with better pharmacokinetics have been synthesized. Arterolane (OZ-277) (Fig. 8) was assessed in clinical trials to treat uncomplicated falciparum malaria. Arterolane showed a rapid action, effectiveness, and safety in Phase II of clinical trials. These results prompted a phase III clinical trial to evaluate the drug in a combination therapy with piperaquine phosphate. As a result of these studies, arterolane was recently registered by Ranbaxy Laboratories Ltd. in India to treat acute uncomplicated malaria [28, 34, 35]. Another ozonide, OZ439 (Fig. 8), showed a remarkable efficacy, cured *P. berghei* infected mice with a single oral dose of 20 mg/Kg, and had a prolonged plasma exposure in animals and humans. It is currently in Phase II, showing good efficacy in the treatment of both *P. falciparum* and *P. vivax* patients. Due to its PK properties, this compound can potentially reach the goal of a single-dose oral cure [28].

Figure 8. Some Compounds in the DDD Pipeline against Malaria, Trypanosomiasis, Leishmania, and Chagas disease

PA1103/SAR116242

Trioxaquinones are hybrid (or chimeric) molecules which target the free heme. These molecules combine two active pharmacophores: a trioxane motif, thought to alkylate the heme and/or the proteins of the *Plasmodium* parasite, and an aminoquinoline moiety to facilitate accumulation in the parasite and interaction with free heme. PA1103/SAR116242 (Fig. 8) is highly active *in vitro* on *P. falciparum* strains at nanomolar concentrations, is also active on multidrug-resistant strains obtained from fresh patient isolates, and is active in the *Pf*-HuMouse models. These promising results combined with a good drug profile (preliminary absorption, metabolism, and safety) have led to further development. Currently, PA1103/SAR116242 is in preclinical stage [36, 37].

DSM265

DHODH has emerged as the best validated new target for the development of novel antimalarials. DHODH catalyzes the fourth step in the de novo pyrimidine biosynthetic pathway. The malaria parasite is uniquely vulnerable to inhibition of this pathway because it lacks the salvage enzymes that serve as an additional source of pyrimidine nucleosides in other organisms, including the human host. DSM265 (Fig. 8) is a potent and selective inhibitor of DHODH and is able to kill both drug-sensitive and drug-resistant strains of the parasite. The compound is currently in Phase I of clinical trials due to its good antimalarial activity, easy synthetic route, and good results in rodent PK studies [38].

Spiroindolones

Spiroindolones were found to inhibit *P. falciparum* *in vitro* with IC₅₀ values around 1 nM. The optimized candidate NITD609 seems to have a different mechanism of action, cured mice infected with *P. berghei*, and showed PK profiles compatible with one-daily oral dosing. The compound has reached clinical Phase IIa [28, 39].

Fexinidazole

Fexinidazole (Fig. 8) is a nitroimidazole active against drug-resistant and drug-sensitive *T. brucei* spp. The compound also cured mice infected with *T. b. rhodesiense* and *T. b. gambiense*, and is able to cross the blood-brain barrier (BBB). Fexinidazole already went successfully through Phase I and currently is under clinical evaluation in Phase IIb/III [13, 28].

SCYX-7158

The oxaborol SCYX-7158 is a boro-containing molecule (Fig. 8) active *in vitro* against both *T. b. rhodesiense* and *T. b. gambiense*. The compound displays an excellent physicochemical profile, showed good efficacy in mice against stage 1 and 2 of the disease, is characterized by *in vitro* metabolic stability, low potential for CYP450 inhibition, lack of active efflux by the P-glycoprotein transporter, and high permeability. SCYX-7158 is currently in Phase I of clinical trials [13, 40].

K777

K777 is a vinyl sulfona (Fig. 8) compound which inhibits the cysteine protease inhibitor cruzain in an irreversible way. Cruzain is a key protease required for the viability of *T. cruzi*. K777 was effective in

acute and chronic Chagas disease models. The compound is currently in pre-clinical phase and *in vivo* pharmacokinetic studies are in process, [13, 32, 41].

VL-2098

VL-2098 is a nitroimidazole with a very potent activity *in vitro* against a panel of *L. donovani* strains. *In vivo*, it is also active in rodent and hamster models with similar potency to miltefosine. Currently the compound is in pre-clinical stage of development [13].

Fenarimol

Fenarimol (Fig. 8) inhibited the proliferation of *Leishmania spp* promastigotes and amastigotes *in vitro* and ameliorated lesions caused by the parasites in mice. Biochemical studies demonstrated that fenarimol inhibited sterol biosynthesis by impairing the function of leishmania 14 α -sterol demethylase, a key enzyme in the sterol biosynthetic pathway. Currently, this compound is in pre-clinical evaluation [13, 42].

- **Screening for Neglected Tropical Diseases (NTD)**

There are two opposing yet complementary screening strategies, namely the target-based and the phenotypic approach (whole organism screening). Both strategies have advantages and disadvantages. However, in the case of antiparasitic drugs, the whole organism screening has a successful historical base. The advantages of this approach are: i) initial chosen hits are cell-permeable and are devoid of efflux issues; ii) provide the opportunity to discover a new target and a potential new mechanism of action; iii) many of the antiprotozoal drugs used today exert their activity through the simultaneous inhibition of multiple targets within a host [4, 23, 43, 44, 45]. Furthermore, NPs are ideally suited for phenotypic screening because they are nature's fully developed small molecules effectors [45].

The target-based approaches have been extensively used in the pharmaceutical industry. However, there are relatively few validated drug targets across the infectious diseases. The target is the key to success in target-based drug discovery. The biology of the pathogens responsible for NTD is very complex and still a lot of research is needed. Nevertheless, the greatest advantage of this approach in NTD is that many proteins and enzymes in the parasite differ from their mammalian counterparts, which enhances the specificity of the drugs [4, 21, 43, 46]. In Table 3, some of the targets are listed.

Table 3. Examples of Molecular Targets for Drug Discovery

Disease	Molecular target	Examples	Ref.
Malaria	Dihydrofolate reductase	Pyrimetamine,	[43]
	Dihydropteroate synthase (DPR)	DPR inhibitor	
	Mitochondrial bc1 complex	Atavaquone	[38, 43]
	Dihydroorotate dehydrogenase (DHODH)		
	Pathway from DOXP to IPP	-	[4]
	Nutrient channels (parasite-encoded nutrient uptake channels in erythrocyte membranes)		[4]
HAT	AMA1 (apical membrane antigen 1)		[4]
	N-Myristoyltransferase		[17, 43]
	Trypanothione synthetase (TryS)		[17, 18, 43, 47]
	Ornithine decarboxylase (ODC)	Eflornithine	[18, 48]
	6-phosphogluconate dehydrogenase		[18]
	Hexokinase, phosphofructokinase		[18]
	Protein farnesyl transferases (PFT)		[17, 18]
	Polyamide pathway enzymes (γ -glutamyl cysteine synthetase, spermidine synthetase)		[18]
Leishmania	CRK3 (Cdc2-Related Kinase 3*)		[43]
	Sterol 14- α -demethylase (CYP51)	Posaconazole, E1224 (prodrug of ravuconazole)	[43]
	Cystein proteinase (CP)	-	[49]
Chagas	TcCa (α -carbonic anhydrase)		[50]
	Cruzipain	K777	[32]

* This is a protein kinase potential for drug targets in kinetoplastid diseases.

- **Critical Pathway for Discovering Neglected Parasitic Diseases**

Establishing a standardized pathway for drug discovery of NTD speeds-up the process and optimizes resources of the international research community. Since the last decade, a standardized system for antimalarial drug screenings emerged, together with a compound progression criteria. In 2009, similar standards were developed for leishmaniasis and HAT (Table 4, Figures 9 and 10) [9, 25].

Table 4. MMV Compound Progression Criteria for Antimalarial Compounds [33]

Test	Consensus
Screening Hits	
Target assay	Biological activity at IC ₅₀ <3 μ M
Cellular assay	Activity against <i>P. falciparum</i> 3D7, HB3, DD2 NF54 or W2 at IC ₅₀ <1 μ M
Validated Hits	
Re-testing	Re-synthesis if necessary to validate results on compound > 90% pure
Activity	IC ₅₀ against biological target (if known) and whole parasites (strains as above) < 1 μ M
Selectivity	Activity against mammalian enzyme and HepG2 cells show > 10-fold sensitivity
Chemistry	Looks drug-like and some initial SAR is established
ADMET	Good predicted computational ADMET properties
Early Leads	
Chemistry	Stable as solid and in test media with good solubility in PBS, initial SAR studies indicate opportunities for chemical targets with straightforward synthesis to yield Rule-of-5 compliant compounds
Biology	IC ₅₀ against biological target (if known) and whole cells < 1 μ M, whole cell activity extends to key drug resistant strains, mode of action known or strategies to address it, depresses parasitemia in mouse model of malaria (oral administration)
ADMET	Stable in human and mouse plasma, reasonable stability with microsomes, CaCo-2 permeability > 2 x 10 ⁻⁶ cm/s, no known toxicophores/reactive groups, no preliminary mouse toxicity
Late Leads	
Chemistry	Structural identification of the compound is confirmed by H and C NMR, LC-MS, and elemental analysis, suitable physicochemical properties, easy, cheap, and environmentally friendly synthesis. Patentable
Biology	IC ₅₀ against biological target (if known) and whole cells < 1 μ M, whole cell activity extends to key drug resistant strains and clinical isolates, ability to clear parasitemia in mouse model of malaria when administered by oral route daily for no more than 4 days with an ED ₅₀ < 10 mg/Kg and ED ₉₀ <30 mg/Kg, using a formulation acceptable for PK and toxicology studies
ADMET	Soluble in PBS at > 20 μ g/mL, stability in human and murine plasma > 90% over 1h, extent of plasma protein binding known, fully PK in rat and dog after oral and iv dosing ok, including oral bioavailability > 20%, hERG and phototoxicity ok, no overt signs of toxicity in <i>in vivo</i> efficacy studies and MTD in mice at least x 10 curative dose

In a typical discovery program for antiprotozoal compounds, the first step is the selection of compounds which show *in vitro* activity against whole-cell assays and sufficient selectivity towards the parasite.

Compounds which match established cut-off values are ranked based on their *in silico/in vitro* ADMET and lead-like/drug-like properties. The best ranked compounds are tested *in vivo* in primary models to test efficacy. Further steps comprise evaluation of mechanisms of action, activity in *in vivo* secondary tests, together with medicinal chemistry and lead optimization efforts. Nowadays the drug-like properties are being screened in parallel with biological activity and constitute a selection criterion [6, 14 22, 23, 51].

Fig 9. New Paradigm for Critical Path of Compound Progression in Antimalarial Drug Discovery from Jimenez-Diaz et al., 2013 [6]

Still, there is the need of more standardization to evaluate the potential of compounds active against trypanosomiasis, Chagas disease, and leishmaniasis. There is i) a lack of reference strains for compound screening, particularly for *T. b. gambiense*; ii) a lack of optimal animal models for testing compounds, particularly for studying some *in vivo* stages, e.g. the “late state” of Trypanosomiasis; iii) immense variability in the behavior among strains which makes it difficult to compare results of laboratories [17, 52, 53].

In this work, the activity of compounds (plant extracts/fractions) was tested in *in vitro* whole-cell assays (Table 5), alongside with testing the cytotoxicity in mammalian cells. The main purpose of the cytotoxicity test was to calculate the selectivity index (SI), which allows the discrimination of attractive compounds from poorly selective molecules.

Fig 10. Algorithm for Screening of Drugs Against HAT and Leishmaniasis [9]

Compounds which complied with selection criteria of the Swiss TPH (Table 5) were challenged in primary *in vivo* models.

This approach was applied not only to malaria but also to HAT, Chagas disease, and leishmaniasis, resulting in an integrated screening approach for tropical diseases. This strategy is a more efficient tool for discovering high-quality hits with good efficiency compared to those which target pathogens individually [23].

Table 5. *In vitro* Activity Criteria [54]

Parasite (strain)	IC ₅₀ activity criteria			
	Active		Mod. activity	Inactive
<i>Plasmodium falciparum</i> (K1/NF54) (intraerythrocytic forms)	< 0.5 μ g/mL SI>100		0.5 – 5 μ g/mL	> 5 μ g/mL
<i>Trypanosoma brucei rhodesiense</i> (STIB900) (blood stream forms)	< 0.5 μ g/mL SI>20		0.2 – 3 μ g/mL	> 3 μ g/mL
<i>Leishmania donovani</i> (axenic amastigotes) (MHOM/ET/67/L82)	< 0.5 μ g/mL SI>20		0.5 – 3 μ g/mL	> 3 μ g/mL
<i>Trypanosoma cruzi</i> (amastigotes in L6 cells) (Tulahuen C2C4 w/LacZ)	< 2 μ g/mL SI>50		2 – 30 μ g/mL	> 30 μ g/mL
Cytotoxicity L6 cells (rat skeletal myoblast cell line)	-		-	-

SI (selectivity index): IC₅₀ mammalian cell / IC₅₀ parasite

- **Natural products and Drug Discovery for NTD**

The antiprotozoal activity of NPs derived from plants, bacteria, fungi, and marine organisms has been extensively studied. Published reviews retrieve this information and show that many secondary metabolites with a wide variety of scaffolds, namely diverse kind of alkaloids, terpenes, and phenolic compounds (e.g. lignans, tannins, coumarins, flavonoids) show potent inhibition on parasites responsible for NTD. Most of the compounds have been assayed in the whole-cell model and in some cases mechanistic studies have been conducted, mainly in the case of malaria and HAT. Despite the promising activity of some NPs, some of them showed limitations such as toxicity, low bioavailability, and/or poor solubility, which restrict their scope of use in humans. Nonetheless, these hits can be modified by semisynthetic approaches to overcome their drawbacks and to boost their benefits [17, 44, 49, 53, 55].

Networking among different areas such as biology, medical chemistry, and pharmacokinetics is required to move forward natural hits and leads through the drug discovery pipeline. The discovery of new validated drug targets and the recent technical progress in the field of NPS chemistry might facilitate this process [17].

Even though, DDD focuses on pure chemical entities, the local and traditional knowledge remains an essential starting point. The observational knowledge about the effect of a plant, an animal, or a microorganism on other organisms offers ideal opportunities to limit the huge diversity of possible leads to more promising ones (knowledge-based drug discovery). Such observational knowledge is exemplified by the discovery of drugs used against parasitic diseases such as malaria [56].

3. RESULTADOS

3.1 *In Vitro* Screening of Traditional South African Malaria Remedies Against *Trypanosoma brucei rhodesiense*, *Trypanosoma cruzi*, *Leishmania donovani*, and *Plasmodium falciparum*

Tsholofelo Mokoka, Stefanie Zimmermann, Tasqiah Julianti, **Yoshie Hata**, Nivan Moodley, Monica Cal, Michael Adams, Marcel Kaiser, Reto Brun, Neil Koorbanally, Matthias Hamburger

Planta Med., 2011, 77: 1663–1667. DOI: 10.1055/s-0030-1270932

Three hundred extracts from 107 South African plant species (42 botanical families) with antiparasitic traditional use were tested against a panel of 4 parasites (*Plasmodium falciparum*, *Trypanosoma brucei rhodesiense*, *Leishmania donovani*, and *Trypanosoma cruzi*). For the most active plants (24), an extensive bibliographic search was performed to select the most promising ones. Ten extracts, corresponding to 10 species, were prioritized to perform HPLC-activity profiles.

My contributions to this work were: (1) literature search for 24 of the active plants in the screening to select the most promising ones to follow up; (2) data interpretation for 34 HPLC-activity profiles performed for 10 selected extracts against P. falciparum, T. b. rhodesiense, and/or L. donovani.

Tasqiah Julianti performed the HPLC-activity profiling of the extracts and Tsholofelo Mokoka wrote the first draft of the paper. The antiprotozoal activity of the extracts and HPLC fractions was assessed at the Swiss TPH. Extracts were provided by the CSIRteam.

Abstract

Three hundred extracts were prepared from plants traditionally used in South Africa to treat malaria and screened *in vitro* for activity against *Trypanosoma brucei rhodesiense*, *Trypanosoma cruzi*, *Leishmania donovani*, and *Plasmodium falciparum*. For the 43 extracts which inhibited the growth of one or more parasites to more than 95% at 9.7 µg/mL, the IC₅₀ values against all four protozoal parasites and cytotoxic IC₅₀s against rat myoblast L6 cells were determined. Amongst

the most notable results are the activities of *Agathosma apiculata* (IC₅₀ of 0.3 µg/mL) against *Plasmodium falciparum*, as well as *Salvia repens* and *Maytenus undata* against *Leishmania donovani* with IC₅₀s of 5.4 µg/mL and 5.6 µg/mL, respectively. This screening is the starting point for a HPLC-based activity profiling project in antiprotozoal lead discovery.

Supporting information available online at <http://www.thieme-connect.de/ejournals/toc/plantamedica>

Introduction

Half a billion people get infected with malaria every year, and 1–2 million die of the disease [1]. Up to thirty million people annually contract one of the so called “neglected tropical diseases”, Chagas disease, human African trypanosomiasis, or leishmaniasis, and the three disorders lead to 120 000 deaths annually [2]. All these diseases are caused by protozoal parasites which are transmitted by insect vectors, and affect the poorest populations. Malaria drugs are reasonably affordable, available, and safe, yet few in number and increasingly compromised by resistances [3]. Only a few drugs are on the market to treat trypanosomatid infections (*Trypanosoma* and *Leishmania*), and their pharmacological profiles are insufficient by modern standards [1]. For decades, large pharmaceutical companies have been reluctant to invest in the development of new drugs for economic reasons. This may be changing though because there have been increasing drug discovery and development efforts in recent years from private initiatives and non-profit organizations. The Medicines for Malaria Venture (MMV), for instance, has initialized research networks [4], and philanthropist organizations like the Bill and Melinda Gates foundation

and others have contributed substantial assets to such endeavors [5].

We report here on the outcome of a screen which is the starting point in the collaboration between the University of Basel, the Swiss Tropical and Public Health Institute, and the South African Council for Scientific and Industrial Research. The goal is to evaluate the antiprotozoal potential of plants used by traditional communities in South Africa to treat malaria. Extracts were screened against the most important protozoal parasites, *Plasmodium falciparum* (malaria), *Trypanosoma cruzi* (Chagas disease), *Trypanosoma brucei rhodesiense* (sleeping sickness), and *Leishmania donovani* (leishmaniasis). This screening study forms the base for an ongoing HPLC-based activity profiling project in antiprotozoal lead discovery. This library had been previously screened for antiplasmodial activity against chloroquine sensitive *Plasmodium falciparum* D10 strain [6].

Material and Methods

Plant species selection

Plants were collected from the wild at various locations in South Africa by different ethnobotanists based on their ethnomedicinal uses against

parasitic diseases, mainly malaria. A list of these uses can be found in an earlier publication [6]. Samples were identified at the South African National Biodiversity Institute (SANBI) by different botanists specializing in specific plant families, and voucher specimens deposited at the South African National Biodiversity Institute (SANBI). The plants project numbers are given in **Table 1S** as Supporting Information.

Preparation of plant extracts

The plant parts (roots, leaves, twigs, fruits, and stem bark) were dried in an oven at 30–60 °C. Dried plant material was ground to a coarse powder using a hammer mill and stored at ambient temperature prior to extraction. Of each sample, 100–500 g of powdered material was sequentially extracted, typically with 1 L of cold dichloromethane (DCM), DCM/methanol (MeOH) (1/1), MeOH, and purified water in 2-L glass jars with screw on lids. The extracts were filtered; the plant material was dried overnight in a fume hood and then extracted with the next more polar solvent. Organic extracts were concentrated using a rotary vacuum evaporator at a temperature below 45 °C and then further dried *in vacuo* at ambient temperature for 24 h. The aqueous extracts were concentrated by freeze-drying. The yields of the extracts, in terms of starting plant material, were recorded. All dried extracts were stored at –20 °C. Analytical grade solvents for extraction were purchased from Romil Pure Chemistry. HPLC grade water was obtained from a TKA Ultra Pure water purification system.

Evaluation of *in vitro* antiprotozoal activity

Screening of the extract library against *Plasmodium falciparum* (K1 strain), *Trypanosoma brucei rhodesiense* (STIB 900 strain), *Trypanosoma cruzi* trypomastigote forms (Tulahuen strain), and *Leishmania donovani* (strain MHOM/ET/67/L82) was performed in 96-well plates at concentrations of 9.7 and 1.8 µg/mL. Tests were done in duplicate and repeated twice. IC₅₀ values against the parasites as well as cytotoxic effects against rat myoblast (L6-cells) were determined by serial dilution and repeated twice. *Trypanosoma brucei rhodesiense* (STIB 900) were grown in axenic medium as described by Baltz et al. [7]. The samples were tested using the Alamar Blue assay protocol [8] to determine the 50% inhibitory concentration (IC₅₀). A Spectramax Gemini XS micro plate fluorescence reader (Molecular Devices Cooperation) with an excitation wavelength of 536 nm and an emission wavelength of 588 nm was used to measure the plates. Melarsoprol (Arsobal®, purity >95%, Sanofi-Aventis) was used as a reference drug (IC₅₀ = 0.03 ± 0.01 µM). The IC₅₀ values were calculated by using Softmax Pro software (Molecular Devices Cooperation). *Trypanosoma cruzi* trypomastigote forms [Tulahuen strain C2C4 containing β-galactosidase (Lac Z) gene] were cultured as described by Buckner et al. [9] in rat myoblast cells (L6-cells). Benzimidazole (purity >95%, Sigma-Aldrich) was used as a standard drug (IC₅₀ = 0.48 µg/mL). After incubation, the substrate chlorophenyl red β-D-galactopyranoside agent CPRG/Nonident was added to all wells, and a color change was developed within 2 to 6 h. The plates were read photometrically at 540 nm (Molecular Devices). Data were evaluated and IC₅₀ values calculated using Softmax Pro software (Molecular Devices).

Axenically grown *L. donovani* amastigotes (strain MHOM/ET/67/L82) were cultured, and tests were done as previously described using the resazurin assay [10]. The plates were developed for 2–4 hours and read on a Spectramax Gemini XS micro plate fluorometer (Molecular Devices) using an excitation wavelength of

536 nm and emission wavelength of 588 nm. Fluorescence development was measured and expressed as a percentage of the negative control. Miltfosine (purity >95%, VWR) was used as a reference drug (IC₅₀ = 0.241 µg/mL). Data were transferred to the graphics program Softmax Pro (Molecular Devices), with which IC₅₀ values were calculated.

Screening of the extract library and determination of activity against *Plasmodium falciparum* K1 strain was done using a modified version of the ³H-hypoxanthine incorporation assay by Trager and Jensen [11]. After incubation the plates were harvested using a Betaplate cell harvester (Wallac) onto glass-fiber filters and washed. The dried filters were inserted into plastic foils with 10 ml scintillation fluid. The radioactivity was counted with a Betaplate liquid scintillation counter (Wallac) as counts per minute per well at each drug concentration and compared to the untreated controls. Chloroquine (purity >95%, Sigma-Aldrich) was used as a positive control (IC₅₀ = 0.05 ± 0.01 µM). IC₅₀ values were calculated by linear interpolation. All assays were run in duplicate and repeated two times.

The cytotoxicity assay was performed by a similar protocol as the Alamar Blue assay whereby L6-cells were seeded in 100 µL RPMI 1640 supplemented in 96-well microtiter plates (4000 cells/well). Podophyllotoxin (purity >95%, Sigma-Aldrich) was used as the reference drug (IC₅₀ = 0.05 ± 0.01 µM). After 68 h of incubation under humidified 5% CO₂ atmosphere, 10 µL of the Alamar Blue marker was added to all wells. The plates were incubated for an additional 2 h. A Spectramax Gemini XS microplate fluorescence reader (Molecular Devices Cooperation) was used to measure the plates (Molecular Devices) using an excitation wavelength of 536 nm and an emission wavelength of 588 nm. The IC₅₀s were calculated by Softmax Pro software (Molecular Devices Cooperation).

Supporting information

A table (**Table 1S**) is provided containing the results of the initial antiprotozoal screen of 300 extracts tested at two concentrations against *Trypanosoma brucei rhodesiense*, *Trypanosoma cruzi*, *Leishmania donovani* and *Plasmodium falciparum*.

Results

One hundred and seven medicinal plants were selected because they had a reported tradition of being used as antiparasitic remedies. Dried plant parts were extracted using solvents of different polarity [DCM, DCM/MeOH (1 : 1), MeOH, and water] to give 300 extracts [6]. In a first step, the extracts were screened for their potential antiparasitic properties against *T. b. rhodesiense*, *T. cruzi*, *L. donovani*, and *P. falciparum* at the test concentrations 9.7 and 1.6 µg/mL (Supporting Information, **Table 1S**).

In a second stage, extracts which in the first step had shown more than 95% inhibition of one or more parasites at a test concentration of 9.7 µg/ml were selected as potential “hits”, and their IC₅₀ values against all four parasites as well as their cytotoxicity against rat myoblast cells (● **Table 1**) were determined. This enabled the direct comparison of activities, parasite specific actions and toxicities of each of our “hits” and served as a basis for the selection of the most promising extracts for HPLC-based activity profiling and identification of the active principles [10].

In general, *P. falciparum* was the most sensitive protozoal parasite towards the extract library. The most potent extract in the entire screen was the DCM/MeOH (1 : 1) extract of *Agathosma apiculata*

Table 1 Antiprotozoal *in vitro* activity (IC₅₀s in µg/mL) of 43 plant extracts against *Trypanosoma brucei rhodesiense*, *Trypanosoma cruzi*, *Leishmania donovani*, and *Plasmodium falciparum*. Extracts were considered “potential hits” when they inhibited one or more of the parasites at 9.7 µg/mL in a preliminary screen (Supporting Information see **Table 1S**). The positive controls melarsoprol, benznidazole, miltefosine, chloroquine, and podophyllotoxin were tested likewise. Tests were done twice in duplicate.

(Rutaceae) with an IC₅₀ of 0.21 µg/mL against *Plasmodium falciparum*. Seven more lipophilic (DCM/MeOH [1:1]) extracts showed antiplasmodial IC₅₀s of under 5 µg/mL: that of *Hypericum aethiopicum* leaves (IC₅₀ = 2.4 µg/mL), *Leonotis leonurus* leaves (2.9 µg/mL), *Ekebergia capensis* fruits (3.5 µg/mL), *Alepidea amatymbica* whole plant (3.7 µg/mL), *Asystasia gangetica* leaves (4.2 µg/mL), *Setaria megaphylla* whole plant (4.4 µg/mL), and *Leo-*

notis ocymifolia var. *ocymifolia* leaves (4.5 µg/mL). Also, the DCM extract of *Leonotis ocymifolia* var. *ocymifolia* leaves was very active (2.7 µg/mL) (● **Table 1**).

Against *Trypanosoma brucei rhodesiense*, the DCM/MeOH (1:1) extracts of *Tarchonanthus camphorates* whole plant (3.9 µg/mL), *Hypericum aethiopicum* leaves (4.7 µg/mL), *Leonotis ocymifolia* var. *ocymifolia* leaves (9.1 µg/mL), *Croton menyhartii* whole plant

(8.8 µg/mL), and the DCM extracts of *Pentzia globosa* roots (5.8 µg/mL), *Vernonia oligocephala* leaves (4.7 µg/mL), *Artemisia afra* leaves (9.6 µg/mL), and *Leonotis ocymifolia* var *ocymifolia* leaves (9.7 µg/mL) showed IC₅₀s lower than 10 µg/mL. Three further DCM, eighteen DCM/MeOH extracts, and one MeOH extract had IC₅₀s between 10 and 20 µg/mL against *Trypanosoma brucei* (● Table 1). Despite the fact that most of the 43 “selected hits” showed relatively good activity against *T. brucei*, none showed selectivity towards this parasite, as it had been the case for the *Plasmodium falciparum* screen.

Trypanosoma cruzi was the least sensitive protozoal test organism. Three extracts, the DCM/MeOH extract of *Hypericum aethiopicum* leaves (18.1 µg/mL), the DCM extract of *Catha edulis* roots (19.1 µg/mL), and the DCM/MeOH extract of *Tarchonardus camphoratus* whole plant (18.6 µg/mL) inhibited *T. cruzi* with IC₅₀s under 20 µg/mL.

Seven extracts showed IC₅₀ of less than 6 µg/mL against *Leishmania donovani*. These were the DCM/MeOH extract of *Hypericum aethiopicum* leaves (4.7 µg/mL), *Leonotis leonurus* leaves (4.7 µg/mL), *Ekebergia capensis* fruits (4.8 µg/mL), *Schefflera umbellifera* (5.0 µg/mL), *Salvia repens* (5.4 µg/mL), *Tachonanthus camphoratus* (4.9 µg/mL), and the DCM extract of *Maytenus undata* (5.6 µg/mL).

Discussion

▼ We screened an extract library generated from plants selected for their traditional antimalarial use against the most important human protozoal parasites. The goal was to identify extracts with potent and, ideally, selective activity against any one of the parasites. These hits are being followed up in an ongoing HPLC-based activity profiling project in antiprotozoal lead discovery.

The initial screening of this focused extract library delivered forty three “potential hits”. These were defined as samples with almost complete (> 95%) inhibition at 9.7 µg/mL. Twelve of them showed activity against *Plasmodium falciparum*, twenty-eight against *Trypanosoma brucei rhodesiense*. Six of these extracts were active against both parasites (Supporting Information, Table 1S). Against *Leishmania donovani* eleven extracts fulfilled the criteria for “potential hits”. Five of these were also active against *T. brucei*. One extract, the DCM extract of *Catha edulis* roots, inhibited both *P. falciparum* and *Leishmania*, and the DCM/MeOH extract of *Hypericum aethiopicum* leaves inhibited the growth of all three parasites. No extract showed > 95% inhibition of *Trypanosoma cruzi* at 9.7 µg/mL. This parasite is generally less sensitive than *Trypanosoma brucei* because it is an intracellular test system.

In a second phase, the IC₅₀s of the 43 “potential hits” were determined against all the parasites and against L6 cells (● Table 1). *Agathosma apiculata* (Rutaceae) was exceptional in the sense that it was by far the most active extract against *Plasmodium falciparum* and showed at the same time good selectivity. An IC₅₀ of 0.3 µg/mL against *Plasmodium* compared to 43 µg/mL in L6 cells corresponded to a selectivity value of 143. The extract was also 140 times more active against *P. falciparum* than against *T. cruzi*, 53 times more active than against *Leishmania donovani*, and 37 times more active than against *T. brucei*.

Nine of the 43 selected active extracts showed IC₅₀s of < 10 µg/mL against *Trypanosoma brucei rhodesiense* (● Table 1). Yet, despite the relatively high activity, none showed selectivity towards this parasite.

Salvia repens and *Maytenus undata* were shown to be preferentially active against *Leishmania donovani*, whilst showing only moderate cytotoxic effects (● Table 1).

The most active extracts against *T. cruzi* showed nonspecific effects. The DCM/MeOH extracts of *Hypericum aethiopicum* leaves (18.1 µg/mL) and *Tarchonardus camphoratus* (18.6 µg/mL) and the DCM extract of *Catha edulis* roots (19.1 µg/mL) at the same time strongly inhibited L6 cells, which are *T. cruzi*'s host cells (● Table 1). The DCM/MeOH and/or DCM extracts of *Hypericum aethiopicum*, *Leonotis leonurus*, *Ekebergia capensis*, *Catha edulis*, *Asystasia gangetica*, *Schefflera umbellifera*, and *Tarchonardus camphoratus* all showed relatively high cytotoxicity, with IC₅₀s < 20 µg/mL, and activities against most protozoal test organisms. Therefore, these extracts were not shortlisted for further follow-up.

In summary, screening of our focused library led to a shortlist of extracts with high activity against *Plasmodium falciparum*, *Trypanosoma brucei rhodesiense*, and *Leishmania donovani* in a primary screen. The percents of inhibition at the two initial test concentrations were roughly indicative of the half maximum inhibition concentration (IC₅₀ values) to be expected in the second stage of the screening. Given the cellular test systems and their inherent variability, some extracts showed IC₅₀s slightly higher or lower than could have been predicted from the primary screen. For direct comparison of activities, it is therefore necessary to determine IC₅₀s by serial dilution (● Table 1). This data, together with cytotoxicity data, helps to determine whether an activity is specific or just a generally toxic effect. Extracts with favorable activities are followed up by HPLC-based activity profiling [12]. We have recently developed and validated a microtiter-based protocol for the miniaturized and efficient identification of antiprotozoal compounds in extracts [10] and successfully applied this approach to the discovery of new antiprotozoal natural products in other library-based discovery projects [13–15]. Results from the profiling and identification of the active principles from the extracts in this screen will be reported in due course.

Conflict of interest

The authors have no conflict of interest.

3.2 Antiprotozoal Screening of 60 South African Plants, and the Identification of the Antitrypanosomal Germacranolides Schkuhrin I and II

Tsholofelo Mokoka, Peter K. Xolani, Stefanie Zimmermann, **Yoshie Hata**, Michael Adams, Marcel Kaiser, Nivan Moodley, Vinesh Maharaj, Neil A. Koorbanally, Matthias Hamburger, Reto Brun, Gerda Fouche

Planta Med., 2013, 79: 1380–1384. DOI: 10.1055/s-0033-1350691

Two hundred and seven extracts from 59 South African plant species (27 botanical families) with antiparasitic traditional use were tested against a panel of 4 parasites (*Plasmodium falciparum*, *Trypanosoma brucei rhodesiense*, *Leishmania donovani*, and *Trypanosoma cruzi*). The 10 most active plants were selected, among them *S. pinnata* and *V. mespilifolia*. The identification of the active compounds from these species was achieved with the aid of HPLC-based activity profiling.

My contributions to this work were: (1) HPLC microfractionation of 10 extract from 5 species; (2) recording and interpretation of analytical data for the 18 HPLC-activity profiles, obtained for the different parasites P. falciparum, T. b. rhodesiense, and/or L. donovani; (3) dereplication of the known constituents of the active fractions; (4) participation in drafting the paper.

Tsholofelo Mokoka performed the HPLC-activity profiling of additional 10 extracts, achieved the isolation of schkuhrin I, II, and cynaropicrin and wrote the first draft of the paper. The antiprotozoal activity of the extracts and HPLC fractions was assessed at the Swiss TPH. Extracts were provided by the CSIR team.

Abstract

Two hundred and seven extracts were prepared from sixty plants from South Africa and screened for *in vitro* activity against *Trypanosoma brucei rhodesiense*, *Trypanosoma cruzi*, *Leishmania donovani*, and *Plasmodium falciparum*. For the 21 extracts which inhibited the growth of one or more parasites with more than 95% at 10 µg/mL, the IC₅₀ values against all four protozoal parasites and cytotoxic IC₅₀ values against L6 myoblasts were determined. Amongst the most notable results are the activities of *Psoralea pinnata* (IC₅₀ of

0.15 µg/mL), *Schkuhria pinnata* (2.04 µg/mL), and *Vernonia mespilifolia* (1.01 µg/mL) against *Trypanosoma brucei rhodesiense*. HPLC-based activity profiling was used to identify the active constituents in the extracts, and the germacranolide sesquiterpene lactones schkuhrin I and II from *S. pinnata*, and cynaropicrin from *V. mespilifolia* were identified, with IC₅₀ values of 0.9, 1.5, and 0.23 µM, respectively.

Introduction

Neglected tropical diseases (NTDs) caused by *Leishmania* species (leishmaniasis), *Trypanosoma brucei* (sleeping sickness), and *Trypanosoma cruzi* (Chagas disease) are life-threatening and represent a risk to large parts of the populations in poor tropical countries. These diseases affect about 21 million people worldwide, mostly in economically challenged regions [1]. It is estimated that these three diseases are responsible for over 110 000 deaths every year [2]. In addition, malaria caused by *Plasmodium* species was responsible for approximately 216 million infections and over 655 000 deaths in 2010 [3]. The control of these parasitic infections relies on a few chemotherapeutic agents, most of which were discovered many decades ago [4] and pose many challenges due to adverse side effects, long treatment cycles, poor efficacy, high costs, the occurrence of drug resistances, and limited availability [1]. Therefore, the discovery of novel, safe, and effective antiprotozoal agents is an urgent need.

Natural products play a significant role in the discovery of new drug leads because of the unmatched availability of chemical diversity. We

previously reported a screen of 300 extracts from plants traditionally used to treat malaria and their antiprotozoal effects against *L. donovani*, *T. b. rhodesiense*, *P. falciparum*, and *T. cruzi* *in vitro* [5]. This work is a continuation of the project, where 207 further extracts have been tested. Furthermore, we report the identification of three antitrypanosomal sesquiterpene lactones from the most active extracts, which were identified by HPLC-based activity profiling [6].

Results and Discussion

A total of 207 plants extracts from 60 plant species were assessed for antiprotozoal activity against four protozoan parasites at 10 and 2 µg/mL, respectively (Table S1 in the Supporting Information). The most active extracts from the preliminary screening were subjected to IC₅₀ value determination. Extracts which exhibited an IC₅₀ value ≤ 5.0 µg/mL were considered active and were subjected to HPLC-based activity profiling to identify potential antiprotozoal compounds. The lipophilic extracts of *Psoralea pinnata* (Fabaceae) and *Drypetes gerrardii* (Euphorbiaceae) exhibited very good antiprotozoal activity

against *T. b. rhodesiense* (IC_{50} , 0.15 ± 0.02 and 0.31 ± 0.02 $\mu\text{g/mL}$) and *P. falciparum* (IC_{50} , 0.50 ± 0.23 $\mu\text{g/mL}$), respectively (● **Table 1**). In addition, these extracts showed the best selectivity index values ranging between 97 and 139, indicating their selectivity towards killing the parasites with very little toxicity towards the myoblasts L-6 cells. *Vernonia mespilifolia* Less. (Asteraceae), *Oedera genistifolia* (Asteraceae), *Abrus precatorius africanus* (Fabaceae), and *Ekebergia capensis* (Meliaceae) also exhibited IC_{50} values ranging between 1.0 and 1.7 $\mu\text{g/mL}$ against *T. b. rhodesiense* and *L. donovani*, however, with moderate selectivity indices ranging from 24 to 48.

The active extracts of *Psoralea pinnata*, *Schkuhria pinnata* (Asteraceae), and *Vernonia mespilifolia* (Asteraceae) were further studied to identify their active constituents. For the purpose of this study, we report the identification of active compounds from *S. pinnata* and *V. mespilifolia* with the aid of an HPLC-based activity profiling technique. However, the identification of active constituents from *P. pinnata* will be reported in a separate publication.

The one minute microfractions from the active DCM/MeOH extract from *Schkuhria pinnata* were tested against *T. b. rhodesiense*, and it was shown that the activity was concentrated in the active time windows of minutes 14 and 16 (● **Fig. 1**), which showed 100% inhibition. These fractions both contained one main substance, which was isolated by semipreparative HPLC and structurally elucidated by NMR, high-resolution MS, and comparison of spectral data to the literature [7]. The compound from fraction 14 was shown to be schkuhrin I (**1**) and the one from fraction 16 was schkuhrin II (**2**) (● **Fig. 3**). The two structurally similar germacranolides showed antiprotozoal activity against *T. b. rhodesiense* with IC_{50} values of 0.86 and 1.50 μM , respectively, and antiparasitodal activity with IC_{50} values of 2.05 and 1.67 μM , respectively (● **Table 2**).

The HPLC activity profile of the DCM/MeOH extract of *V. mespilifolia* showed significant antiprotozoal activity in fractions 12 and 13 against *T. b. rhodesiense* (● **Fig. 2**). The compound was isolated, and, by use of NMR, high-resolution MS, and comparison to literature data [8], identified as the known sesquiterpene lactone cynaropicrin (**3**) (● **Fig. 3**). The IC_{50} s of **3** were 0.23 μM against *T. b. rhodesiense* and 1.56 μM against *P. falciparum*. *L. donovani* exhibited an IC_{50} value of 1.56 μM , whereas *T. cruzi* was the least susceptible parasite with an IC_{50} value of 5.14 μM .

This study is a continuation of our efforts of collecting and screening South African plants against protozoan parasites [5]. The results of a large screen of 207 extracts are shown (Supporting Information **Table S1**). Furthermore, by using HPLC-based activity profiling, the sesquiterpene lactones schkuhrin I (**1**) and II (**2**) from *Schkuhria pinnata*, and cynaropicrin (**3**) from *Vernonia mespilifolia*, were identified as potent antiprotozoal agents. The powdered leaf of *S. pinnata* has been used as a remedy for malaria, influenza, and colds [9]. Also, *S. pinnata* has been used as an insecticide, particularly to kill fleas [11]. Extracts from *S. pinnata* were shown to inhibit *Brucella abortus* *in vitro* [10], and have yielded several sesquiterpene lactones and the phenyl propanoids [11]. Both schkuhrin I (**1**) and II (**2**) have been isolated from the same species and other *Schkuhria* species, but their antiprotozoal activities have not been reported previously.

Some of the species belonging to the genus *Vernonia* have been used in folk medicine to treat malaria [12]. *V. mespilifolia* Less. is used traditionally by Zulus to treat malaria-related feverish conditions [13].

Sesquiterpenes are the largest known group of natural products [14] and are a chemical marker for the largest plant family, the Asteraceae [15]. Numerous sesquiterpene lactones have been tested for antiprotozoal activity *in vitro*. Schmidt et al. [16] showed in an antitrypanosomal-QSAR study of 40 STLs and, in 2012, supplied two excellent reviews of antiprotozoal *in vitro* effects of 883 plant-derived natural products including 83 sesquiterpene lactones [14, 16]. This study is the first report of the antiprotozoal effects of **1** and **2**, whereas the antitrypanosomal effects of **3** have already been described by Zimmermann et al. [17]. In fact, **3** was the first and so far only plant-derived compound to inhibit *T. b. rhodesiense* *in vivo*. The mode of action of **3** was shown to be its ability to form stable bis-adducts with trypanothione via a Michael addition, thus depleting the parasites of their only means of redox control [18].

With this screening study we report recent *in vitro* results of a plant extract screen. This may provide a basis for selecting plants in the future for further phytochemical and bioactivity studies. Furthermore, we report the *in vitro* antiprotozoal effects of three compounds, which will contribute to a better understanding of sesquiterpene lactones antiprotozoal structure-activity relationships.

Materials and Methods

Plant collection and identification

Sixty plant species were collected between 1996 and 2002 at a variety of locations in South Africa. The selected plant species were based on their traditional uses against parasitic diseases (unpublished work). The species were identified by personnel of the South African National Biodiversity Institute (SANBI) where the voucher specimens were deposited (**Table S1** in the Supporting Information).

Plant extract preparations

The plant parts (roots, leaves, twigs, fruit, and stem bark) were dried in an oven at 30–60°C, and extracts from finely ground plant parts were prepared as previously described [5]. Stock solutions were prepared at 10 mg/mL in DMSO and stored at –80°C until use. Dilutions for biological testing were freshly prepared in culture medium on the day of testing (< 1% DMSO).

Isolation and purification of active compounds **1**, **2**, and **3**

For compounds **1**, **2**, and **3**, semipreparative HPLC purification was performed using an Agilent HPLC 1200 series consisting of a low-pressure mixing pump with a degasser module, column oven, and PDA detector (Agilent). The extracts of the whole plant of *Schkuhria pinnata* (Lam.) Cabrera and *Vernonia mespilifolia* Less. (100 mg/mL in DMSO, respectively) were prepared by dissolving 1.0 g of DCM/MeOH (1:1) extract, filtered through 0.45 μm Millipore membrane filters. Several repetitions of 200 μL injections were made. The separation was performed on a Waters Sunfire RP-18 column (10 \times 150 mm i.d.; 10 μm ; Waters GmbH). The mobile system used was made up of water (A) and acetonitrile (B). The elution gradient was linear from A:B (90:10) to (0:100) in 30 min at a flow rate of 6.0 mL/min, followed by 5 min of acetonitrile washing, and returned to the initial elution conditions (90:10) over 5 min. The separation of all components was detected at a wavelength of 254 nm.

Table 1 The IC₅₀ values ± standard deviation (µg/mL), selectivity index, and cytotoxicity of 18 South African plant species against *Trypanosoma brucei rhodesiense*, *Trypanosoma cruzi*, *Leishmania donovani*, *Plasmodium falciparum*, and myoblast L6 cells. The positive controls melarsoprol^a, benznidazole^b, miltefosine^c, chloroquine^d, and podophyllotoxin^e were tested likewise. Tests were done twice in duplicate.

Biological assays

All extracts were screened as previously described [5] against *P. falciparum* (NF-54 strain), *T. b. rhodesiense* (STIB 900 strain), *T. cruzi* trypomastigote forms (Tulahuen strain), and *L. donovani* (strain MHOM/ET/67/L82) at 10 (high concentration) and 2 $\mu g/mL$ (low concentration). Half maximal inhibition concentrations (IC_{50} s) were determined by serial dilution, and represent the

mean of at least two independent experiments. HPLC-based activity profiling was done as previously described [7]. Positive controls, melarsoprol (Sanofi-Aventis) (*T. b. rhodesiense*), benznidazole (Sigma) (*T. cruzi*), miltefosine (VWR) (*L. donovani*), chloroquine (Sigma) (*P. falciparum*), and podophyllotoxin (Sigma) (L6 cells) were used. The purity of all controls was >95% according to the suppliers.

Fig. 3 Structures of the isolated compounds from *Schkuhria pinnata* and *Vernonia mespilifolia* crude extracts.

Supporting information

Data on the antiprotozoal activity of 60 South African medicinal plants, protocols for the purification and isolation of schkuhrin I, schkuhrin II, and cynaropicrin, as well as detailed protocols for the bioassays are available as Supporting Information.

Purification and isolation of schkuhrin I and schkuhrin II

The (DCM/MeOH; 1:1) extract of *Schkuhria pinnata* (8.0 g) was suspended in a mixture of methanol and dichloromethane and chromatographed on silica gel 60 (80 g). The column was initially eluted with a mixture of hexane (Hex) and ethyl acetate (EtOAc) (1:1). Twenty fractions of 50 mL each were collected and thereafter the polarity was increased to Hex:

EtOAc (4:6) and a further twenty-six fractions collected. Finally, the polarity was increased to 100% EtOAc and 30% methanol (MeOH), respectively. The collected fractions were analysed using thin-layer chromatography (TLC) plates and similar fractions were combined resulting in twelve (A-L) fractions. Semipreparative RP-HPLC purification was employed using a SunFire™ C18 column (3.5 µm, 10 × 150 mm; Waters) with H₂O (solvent A) and MeCN (solvent B) to give fraction I (950 mg) and fraction J (300 mg) which were further purified to yield schkuhrin I (**1**) (250 mg) and schkuhrin II (**2**) (120 mg), respectively. The structures and stereochemistry of **1** [6] and **2** [6] were compared to that of published data and the purity of the compounds was > 95% as determined by the NMR data.

Purification and isolation of cynaropicrin (3**)**

The (DCM/MeOH; 1:1) extract of *Vernonia mespilifolia* (1.0 g) was suspended in chloroform and chromatographed on silica gel 60 (10 g). The column was eluted with a mixture of hexane (Hex) and ethylacetate (EtOAc) (6:4). Finally, the polarity was increased to 30% methanol (MeOH). The collected fractions (50 mL) were monitored by TLC and similar fractions were combined. Fraction J (30 mg) was further purified by semipreparative RP-HPLC using a SunFire™ C18 column (3.5 µm, 10 × 150 mm; Waters) with H₂O (solvent A) and MeCN (solvent B), resulting in the isolation of cynaropicrin (**3**) (11.0 mg). The structure of **3** [7] was compared to that of published data and the purity of cynaropicrin (**3**) was > 95% as determined by NMR.

Bioassays

a. In vitro* test against *Trypanosoma brucei rhodesiense

Trypanosoma brucei rhodesiense (STIB 900) were grown in axenic medium as previously described [3]. The compounds were tested using a modified Alamar Blue assay protocol [4] to determine the 50% inhibitory concentration (IC₅₀). Serial threefold drug dilutions were prepared in 96-well microtitre plates and 50 µL of *T. b. rhodesiense* STIB 900 bloodstream

forms were added to each well except for the negative controls. Melarsoprol (Arsobal®; Sanofi-Aventis) was used as a reference drug. After 70 h of incubation, the Alamar Blue marker (12.5 mg resazurin dissolved in 100 mL distilled water) was added. The plates were then incubated for an additional 2 to 5 h. A Spectramax Gemini XS microplate fluorescence reader (Molecular Devices Cooperation) with an excitation wavelength of 536 nm and an emission wavelength of 588 nm was used to read the plates. The IC₅₀ values were calculated from the sigmoidal growth inhibition curves using Softmax Pro software (Molecular Devices).

b. In vitro testing against Plasmodium falciparum

A modification of the [³H]-hypoxanthine incorporation assay was used to determine the intra-erythrocytic antiplasmodial activity (Desjardins 1979) of the extract library and purified compounds in 96-well plates. Chloroquine (Sigma-Aldrich) and artesunate (Mepha) were used as standard drugs. Briefly, infected human red blood cells in RPMI 1640 medium (100 µL per well with 2.5% haematocrit and 0.3% parasitaemia) were exposed to twofold serial drug dilutions in 96-well microtitre plates. After 48 h incubation, 0.5 µCi [³H]-hypoxanthine was added to each well. The plates were incubated for a further 24 h before being harvested using a Betaplate cell harvester (Wallac). The radioactivity was counted with a Betaplate liquid scintillation counter (Wallac) as counts per minute per well at each drug concentration and compared to the untreated controls. IC₅₀ values were calculated from sigmoidal inhibition curves using Microsoft Excel. All assays were run in duplicate and repeated three times [5].

c. In vitro cytotoxicity testing

Cytotoxicity was assessed using a similar Alamar Blue assay protocol [3] whereby 4000 rat myoblast cells/well were seeded in RPMI 1640 medium. All following steps were according to the *T.b. rhodesiense* protocol. Podophyllotoxin (Sigma-Aldrich) was used as the reference drug.

3.3 Antiprotozoal Isoflavan Quinones from *Abrus precatorius* ssp. *africanus*

Yoshie Hata, Melanie Raith, Samad Nejad Ebrahimi, Stefanie Zimmermann, Tsholofelo Mokoka, Dashnie Naidoo, Gerda Fouche, Vinesh Maharaj, Marcel Kaiser, Reto Brun, Matthias Hamburger

Planta Med., 2013, 79: 492–498. DOI: 10.1055/s-0032-1328298

HPLC-based activity profiling allowed the identification of 5 isoflavanquinones from *Abrus precatorius*. Two of them were new compounds and one was a new natural product. Abruquinones I and B showed strong *in vitro* activity against *Trypanosoma brucei rhodesiense* and remarkable selectivity. These results classified abruquinones I and B for *in vivo* evaluation of their trypanocidal activity.

My contributions to this work were: (1) HPLC microfractionation; (2) isolation of isoflavanquinones; (3) recording and interpretation of analytical data for structure elucidation (HPLC-PDA-ESI-MS, TOF-MS, 1D and 2D NMR, CD measurements) and other measurements such as optical rotation; (4) writing of the first draft of the manuscript, preparation of figures, tables, and supporting information.

Samad Ebrahimi did the quantum-chemical calculation of ECD spectra, and under his supervision I participated in the respective data analysis. Melanie Raith supervised structure elucidation. In vitro tests were performed by Stefanie Zimmermann and the team of the Swiss TPH. The crude extract was provided by the CSIR team.

Abstract

A library of 206 extracts from selected South African plants was screened *in vitro* against a panel of protozoan parasites, *Plasmodium falciparum*, *Trypanosoma brucei rhodesiense*, and *Leishmania donovani*. A CH₂Cl₂/MeOH (1:1) extract of *Abrus precatorius* L. ssp. *africanus* strongly inhibited *P. falciparum* (98%), *T. b. rhodesiense* (100%), and *L. donovani* (76%) when tested at a concentration of 10.0 µg/mL. The active constituents were tracked by HPLC-based activity profiling and isolated by preparative and semipreparative RP-HPLC chromatography. Structures were established by HR-ESIMS, and 1D and 2D NMR (¹H, ¹³C, COSY, HMBC, HSQC, and NOE difference spectroscopy). Five compounds were obtained and identified as two isoflavan hydroquinones, abruquinone H (1) and abruquinone G (2), and three isoflavan quinones, abruquinone I (3), abruquinone B (4), and 7,8,3',5'-tetramethoxyisoflavan-1',4'-quinone (5). Compounds 1 and 3 were new natural products. The absolute configuration of compounds was determined by comparison of electronic circular dichroism spectra with calculated ECD data. Compounds 3 and 4 showed strong activity against *T. b. rhodesiense* (IC₅₀ values of 0.30

and 0.16 µM, respectively) and good selectivity (selectivity indices of 73.7 and 50.5, respectively).

Introduction

NTDs affect the lives of a billion people worldwide, in particular in developing countries. Some of these are caused by protozoan parasites, such as HAT, leishmaniasis, malaria, and Chagas disease. The responsible parasites are *Trypanosoma brucei rhodesiense* and *T. b. gambiense* (HAT), *Leishmania* sp., *Plasmodium* spp. (*P. falciparum*, *P. vivax*, *P. ovale*, *P. malariae*, and *P. knowlesi*), and *Trypanosoma cruzi*, respectively [1,2]. These diseases cause an enormous burden, and according

to the WHO, HAT is accountable for 1 673 000, leishmaniasis for 1 974 000, malaria for 33 976 000 and Chagas for 430 000 DALYs [1,3]. Drugs currently available to treat these illnesses are old, limited in efficacy, and cause severe side effects [4,5]. Hence, new drugs with better therapeutic profiles are urgently needed. Natural products such as quinine and artemisinin have significantly contributed to the development of modern antiprotozoal drugs. We have recently embarked on a library-based discovery of natural product leads with antiprotozoal activity [6–9]. In

a library of 206 extracts prepared from ethnobotanically preselected medicinal plants from South Africa, a $\text{CH}_2\text{Cl}_2/\text{MeOH}$ (1 : 1) extract from aerial parts of *Abrus precatorius* L. ssp. *africanus* Verdc. (Fabaceae) strongly inhibited *P. falciparum* (98%), *T. b. rhodesiense* (100%), and *L. donovani* (76%) when tested at a concentration of 10.0 $\mu\text{g}/\text{mL}$. In contrast, it did not show inhibition against *T. cruzi*.

A. precatorius is a climber shrub native from India but now also grows in other regions of the world [10–12]. The seeds are highly toxic due to abrin, a ribosome-inactivating lectin [10]. However, leaves and roots are used in folk medicine to treat different conditions like skin diseases, hepatitis, bronchitis, laryngitis, and malaria [13–15]. Antiplatelet, anti-inflammatory, antiallergic [13], antimalarial [14, 15], and antitubercular activities [16] have been reported. A spectrum of secondary metabolites have been identified from *A. precatorius*, including triterpenoids [12, 17, 18], alkaloids [19], flavonoids [12, 20], and isoflavanquinones [11, 13, 16, 21]. We report here on the localization and identification of active isoflavan quinones from the extract with the aid of HPLC-based activity profiling [6, 22], determination of absolute configuration by ECD, and *in vitro* testing of pure compounds.

Materials and Methods

General experimental procedures

HPLC-grade methanol (MeOH), acetonitrile (MeCN) (Scharlau Chemie S.A.), and water (obtained by an EASY-pure II from Barnstead water purification system) were used for HPLC separations. HPLC solvents contained 0.1% HCOOH (Sigma) for analytical separations. Chloroform-*d* (100 atom% D) and methanol-*d*₄ (100 atom% D) for NMR were purchased from Armar Chemicals. Solvents used for extraction were of analytical grade (Romil Pure Chemistry). Reference drugs for bioassays were artesunate (purity > 95%; Mepha), melarsoprol (purity > 95%; Sanofi-Aventis), benznidazole (purity > 95%; Sigma-Aldrich), miltefosine (purity > 95%; VWR), and podophyllotoxin (purity > 95%; Sigma-Aldrich). HPLC-PDA-MS analyses were performed with an Agilent 1100 system consisting of a degasser, a quaternary pump, a column oven, a PDA detector connected to a Gilson 215 injector and to an Esquire 3000 plus ion trap mass spectrometer (Bruker Daltonics). Data acquisition and processing were performed using HyStar 3.0 software (Bruker Daltonics). Preparative HPLC was carried out on a Shimadzu LC-8A instrument equipped with a SCL-10A VP system controller, an LC-8A pump, an SPD-M10A VP PDA detector, and VP 6.14 SP2A control software. Semipreparative HPLC was performed with an Agilent 1100 series instrument equipped with a PDA detector. Data acquisition and processing were performed using HyStar 3.2 software (Bruker Daltonics). Chromatographic purity of the isolated compounds was assessed on an Alliance 2695 HPLC system (Waters) equipped with 996 PDA (Waters) and Alltech 2000ES ELSD detectors. For HR-ESIMS, a microTOF ESI-MS system (Bruker Daltonics) was used. Mass calibration was performed with a solution of formic acid 0.1% in 2-propanol/water (1 : 1) containing 5 mM NaOH. Mass spectra were recorded in the range of m/z 150–1500 in the positive ion mode with the aid of microTOF control software 1.1 (Bruker Daltonics). NMR spectra were recorded on a Bruker AVANCE III™ 500 MHz spectrometer equipped with a 1-mm TXI microprobe (¹H and 2D NMR) or a 5-mm BBO probe (¹³C NMR) (Bruker Bio-Spin) operating at 500 (¹H) and 125 MHz (¹³C). Chemical shifts are reported as δ values (ppm) with the residual solvent signal

as the internal reference, J in Hz. Standard pulse sequences from Topspin 2.1 software package were used. Further spectroscopic data were acquired on a Hewlett Packard 8453 photometer (UV), an AVIV CD spectrometer Model 62ADS (CD), and a Perkin Elmer polarimeter (model 341) equipped with a 1-dm microcell (OR).

Plant material

Samples of the whole plant of *A. precatorius* were collected at Jozini, KwaZulu Natal Province in South Africa during November 2001 by a botanist, Mr. Hans Vahrmeijer. A plant specimen was deposited at the South African National Biodiversity Institute (SANBI), and the plant was identified as *Abrus precatorius* L. ssp. *africanus* Verdc. (Fabaceae) (voucher specimen number PRE 442421).

Extraction

The whole plant was dried in an oven at 30–60 °C. Dried plant material was ground to a coarse powder using a hammer mill and stored at ambient temperature prior to extraction. 200 g of dried, ground material was extracted with 1 L of a mixture of CH_2Cl_2 and MeOH (1 : 1) at room temperature for 1 h with occasional stirring. The solvent was filtered, and the residual plant material was further extracted overnight with 500 mL $\text{CH}_2\text{Cl}_2/\text{MeOH}$ (1 : 1) followed by filtration. Finally, a third extraction of the pulp was done with 500 mL solvent for 1 h with filtration. The pulp was discarded, and the filtrates combined and concentrated using a rotary vacuum evaporator at a temperature below 45 °C and then further dried *in vacuo* at room temperature for 24 h. The dried extract of 15.4 g (7.7%, w/w) was stored at –20 °C.

Microfractionation and activity profiling

Microfractionation for HPLC-activity profiling was performed as previously described [6], on a SunFire™ C18 column (3.5 μm , 3.0 × 150 mm; Waters) with H₂O (solvent A) and MeCN (solvent B) using the following gradient profile: 10% → 100% B (0–30 min), 100% B (31–32 min). The flow rate was 0.5 mL/min. 35 μL of a solution of the extract (10 mg/mL in DMSO) was injected. 32 one-minute fractions were collected by the aid of a F204 fraction collector (Gilson) into a 96-deep-well plate (Eppendorf). After solvent removal in an Evaporex 96 channel N₂-evaporator (Apricot Designs), the dried fractions were redissolved in methanol (100 μL) and transferred to 96-v-well plates (Thermo Scientific), dried again, and stored in a refrigerator (2–8 °C) until assayed.

Preparative isolation of abruquinones

For isolation of compounds, 850 mg of a $\text{CH}_2\text{Cl}_2/\text{MeOH}$ (1 : 1) extract of the whole plant was separated in a SunFire™ RP-C18 column (5 μm , 30 mm × 150 mm; Waters) with a gradient consisting of H₂O (solvent A) and MeOH (solvent B) as follows: 10% → 100% B (0–30 min), 100% B (31–35 min). The flow rate was 20 mL/min. The extract was dissolved in DMSO at a concentration of 100 mg/mL, and aliquots of 380 μL were injected. Fraction 1 (28.1 mg, t_R 21.0 min), fraction 2 (33.2 mg, t_R 22.8 min), fraction 3 (29.8 mg, t_R 23.8 min), and fraction 4 (47.6 mg, t_R 25.3 min) were collected and purified by semipreparative RP-HPLC using a SunFire™ C18 column (3.5 μm , 10 × 150 mm; Waters) with H₂O (solvent A) and MeCN (solvent B) and the following gradient: 10% → 100% B (0–30 min), 100% B (31–35 min). The flow rate was 5 mL/min. The fractions were dissolved in DMSO (10 and 20 mg/mL, depending on their solubility) and injected in aliquots of 250 μL . Compound

1 (1.7 mg, t_{R} 12.0 min) was obtained from fraction 1. Compounds **2** (3.9 mg, t_{R} 14.6 min) and **3** (5.8 mg, t_{R} 14.3 min) were isolated from fraction 2. Compounds **4** (14.7 mg, t_{R} 16.2 min) and **5** (2.4 mg, t_{R} 16.8 min) were purified from fractions 3 and 4, respectively. Purity of compounds **1** and **3–5** was > 95% as determined by ^1H -NMR and HPLC-ELSD analyses. Compound **2** showed a single peak in HPLC analysis, but the ^1H NMR spectrum revealed the presence of about 15% of an unidentified related metabolite (Fig. 5S, Supporting Information).

(3S)-4R)-4,8,1',4'-tetrahydroxy-6,7,2',3'-tetramethoxyisoflavan (abruquinone **H**, **1**): Colorless amorphous substance; UV (MeOH): λ_{max} (log ϵ) = 206 (4.59), 295 (3.67) nm; $[\alpha]_{\text{D}}^{18}$: –192 (c = 0.1, MeOH); CD (MeOH): $\Delta\epsilon_{212\text{ nm}}$ = –31.5, $\Delta\epsilon_{238\text{ nm}}$ = –6.89 (sh), $\Delta\epsilon_{285\text{ nm}}$ = –1.02, $\Delta\epsilon_{302\text{ nm}}$ = +1.43; ^1H and ^{13}C NMR data in CDCl₃ and CD₃OD, see Table 1; HR-ESIMS: m/z = 399.1023 [M – H₂O + Na]⁺ (calcd. for C₁₉H₂₂NaO₉: 399.1050).

(3S)-4R)-4,1',4'-trihydroxy-6,7,8,2',3'-pentamethoxyisoflavan (abruquinone **G**, **2**) [16]: For physicochemical characterization, see Supporting Information. $[\alpha]_{\text{D}}^{18}$: –59.9 (c = 0.1, MeOH); CD (MeOH): $\Delta\epsilon_{215\text{ nm}}$ = –49.0; $\Delta\epsilon_{232\text{ nm}}$ = –12.2; $\Delta\epsilon_{285\text{ nm}}$ = –2.24; $\Delta\epsilon_{304\text{ nm}}$ = +4.35.

(3R)-8-hydroxy-7,3',5'-trimethoxyisoflavan-1',4'-quinone (abruquinone **I**, **3**): Yellow amorphous substance; UV (MeOH): λ_{max} (log ϵ) = 205 (4.58), 286 (4.07) nm; $[\alpha]_{\text{D}}^{19}$: +21.0 (c = 0.1, MeOH); CD (MeOH): $\Delta\epsilon_{212\text{ nm}}$ = +8.40, $\Delta\epsilon_{215\text{ nm}}$ = +4.84, $\Delta\epsilon_{233\text{ nm}}$ = –0.62, $\Delta\epsilon_{256\text{ nm}}$ = +0.20, $\Delta\epsilon_{283\text{ nm}}$ = –0.20, $\Delta\epsilon_{305\text{ nm}}$ = +0.06; ^1H and ^{13}C NMR data in CDCl₃, see Table 1; HR-ESIMS: m/z = 369.0908 [M + Na]⁺ (calcd. for C₁₈H₁₈NaO₇: 369.0945).

(3S)-7,8,3',5'-tetramethoxyisoflavan-1',4'-quinone (**5**) [23]: For physicochemical characterization, see Supporting Information. $[\alpha]_{\text{D}}^{20}$: –1.3 (c = 0.1, CHCl₃); $[\alpha]_{\text{D}}^{19}$: –19 (c = 0.1, MeOH); CD (MeOH): $\Delta\epsilon_{216\text{ nm}}$ = –6.74; $\Delta\epsilon_{238\text{ nm}}$ = –3.62; $\Delta\epsilon_{274\text{ nm}}$ = –0.37; $\Delta\epsilon_{294\text{ nm}}$ = +0.39.

Conformational analysis, geometrical optimization, and ECD calculation

Conformational analysis of **2**, **3**, **4**, and **5** was accomplished with Schrödinger MacroModel 9.1 software employing the OPLS 2005 (optimized potential for liquid simulations) force field in H₂O. Conformers within a 1 Kcal/mol energy window from the global minimum were picked for geometrical optimization and energy calculation applying DFT with the Becke's nonlocal three parameter exchange and correlation functional, and the Lee-Yang-Parr correlation functional level (B3LYP) using the 6–31 G** basis set in the gas phase with the Gaussian 09 program package [24]. Vibrational evaluation was done at the same level to confirm minima. Excitation energy (denoted by wavelength in nm), rotator strength dipole velocity (R_{vel}), and dipole length (R_{len}) were calculated in MeOH by TD-DFT/B3LYP/6–31 G**, using the SCRF method, with the CPCM model. ECD curves were obtained on the basis of rotator strengths with a half-band of 0.2 eV using SpecDis v1.51 [25]. The spectra were combined after Boltzmann weighting according to their population contribution.

Bioassays

The antiprotozoal activity of the CH₂Cl₂/MeOH (1:1) extract of *A. precatorius* was tested *in vitro* against *Plasmodium falciparum* (K1 strain), *Trypanosoma brucei rhodesiense* (STIB 900 strain), *Trypanosoma cruzi* (Tulahuen strain C2C4 w/LacZ), and *Leishmania donovani* (strain MHOM/ET/67/L82), in 96-well microtiter plates at concentrations of 10.0 $\mu\text{g/mL}$ and 2.0 $\mu\text{g/mL}$. HPLC mi-

Fig. 1 HPLC-based activity profiling of *A. precatorius* extract for antiprotozoal properties. HPLC chromatogram (190–700 nm) for 32 one-minute fractions from 350 µg of extract (**A**) and inhibition (in %) of three different parasites *P. falciparum* (**B**), *T. b. rhodesiense* (**C**), and *L. donovani* (**D**) by the time-based collected fractions.

crofractionations were assayed against *P. falciparum*, *T. b. rhodesiense*, and *L. donovani*. Isolated compounds were evaluated for their antiprotozoal activity using the parasites as described above. Additionally, cytotoxicity was determined using the rat skeletal myoblast cell line (L-6 cells). For the assays, DMSO stock solutions (10 mg/mL) of extracts and purified compounds were each time freshly diluted in medium (final DMSO concentration in assay <1%). Assays were performed with three independent repetitions, except for *L. donovani*. Details on culturing of parasites and assay protocols are provided as Supporting Information.

Supporting information

Detailed protocols of biological activity, NMR spectra (1D and 2D) of compounds **1** and **3**, ^1H NMR spectra of all compounds, physicochemical and spectroscopic data of compounds **2**, **4**, and **5**, as well as experimental and calculated ECD spectra of all compounds are provided.

Results and Discussion

The $\text{CH}_2\text{Cl}_2/\text{MeOH}$ (1:1) extract of *A. precatorius* inhibited *P. falciparum* (98%) and *L. donovani* (76%) at a concentration of 10.0 µg/mL. Additionally, it completely inhibited *T. b. rhodesiense* (100%) at 2.0 µg/mL. In contrast, the extract did not show any activity against *T. cruzi* at these concentrations. The extract was submitted to HPLC-based activity profiling using a previously validated protocol [6]. An aliquot (350 µg) of the extract was separated by analytical HPLC, and 32 one-minute microfractions were collected into a 96-deep-well plate. After drying, they were tested against *P. falciparum*, *L. donovani*, and *T. b. rhodesiense*. The HPLC chromatogram and the corresponding activity profiles are shown in **Fig. 1**. The chromatogram showed strong UV-absorbing peaks at t_{RS} = 12.9, 14.8, 15.3, 15.8, 17.3, and 18.0 min. In this time window (minutes 13–18), inhibition of *P. falciparum*, *L. donovani*, and *T. b. rhodesiense* was observed, corresponding to fractions 15 and 17 (*P. falciparum* by 54% and 99%, respectively),

fractions 14 to 16 (*L. donovani* by 62% and 64%, respectively), and fractions 13 and 14 to 18 (*T. b. rhodesiense* by 99% to 100%).

Isolation of compounds **1–5** (**Fig. 2**) in the active time window was achieved by preparative RP-HPLC followed by final purification on semipreparative RP-HPLC. Structures were established by NMR spectroscopy (^1H , ^{13}C , COSY, HSQC, and HMBC), HR-ESIMS, and ECD. Compounds **2** [(3*S*-4*R*)-4,1',4'-trihydroxy-6,7,8,2',3'-pentamethoxyisoflavan] and **4** [(3*R*)-6,7,8,2',3'-pentamethoxyisoflavan-1',4'-quinone] have been reported as abruquinones G and B, respectively [11,13,16,21]. Compound **5** [(3*S*)-7,8,3',5'-tetramethoxyisoflavan-1',4'-quinone] has been previously described as a synthetic derivative but not as a natural product [23]. Compounds **1** [(3*S*-4*R*)-4,8,1',4'-tetrahydroxy-6,7,2',3'-tetramethoxyisoflavan] and **3** [(3*R*)-8-hydroxy-7,3',5'-trimethoxyisoflavan-1',4'-quinone] are new and have been designated as abruquinone H and abruquinone I, respectively.

A molecular formula of $\text{C}_{19}\text{H}_{22}\text{O}_9$ for compound **1** was deduced from HR-ESIMS (m/z 399.1023 [$\text{M} - \text{H}_2\text{O} + \text{Na}$] $^+$; calcd.: 399.1050). The formula accounted for 9 degrees of unsaturation. The ^1H and ^{13}C NMR spectra (**Table 1**) showed 18 proton and 19 carbon signals, respectively. Twelve of the carbon signals were in the region between δ_{C} 103.9 and 147.7, and were indicative of a highly substituted aromatic ring system. The ^1H NMR spectrum in CDCl_3 (**Table 1**) displayed four singlets of aromatic methoxy groups (δ_{H} 3.96, 3.90, 3.89, and 3.85), in accordance with four carbon signals at δ_{C} 60.9, 60.9, 60.3, and 56.3. Additionally, the ^1H NMR spectrum showed four aliphatic signals at δ_{H} 5.43 (d, J = 7.0 Hz), 4.30 (dd, J = 10.7, 5.1 Hz), 3.66 (dd, J = 10.7, 11.1 Hz), and 3.51 (m), suggesting an isoflavan scaffold with a hydroxyl group at C-4. Unambiguous assignment of ^1H and ^{13}C NMR data was achieved by a combination of COSY, HMBC, HSQC, and NOE difference experiments, together with the comparison with reported data of abruquinones and -hydroquinones [11,13,16,21]. The connectivity of the rings as well as the positions of the methoxy groups were determined with the aid of HMBC correlations (**Fig. 3**). The connectivity of rings A and C was confirmed by $^3J_{\text{C-H}}$ coupling between C-9 (δ_{C} 138.3) and H-5 (δ_{H} 6.62, ring A) and H-4 (δ_{H} 5.43, ring C). An HMBC correlation between H-3 (δ_{H} 3.51, ring C) and C-6' (δ_{C} 122.4, ring B) corroborated the connectivity between rings B and C and the presence of an isoflavan scaffold. The vicinal coupling constants H-2 α /H-3 (J = 5.1 Hz) and H-2 β /H-3 (J = 11.1 Hz) corresponded to dihedral angles of 60° and 180°, respectively, indicating an axial orientation of H-3. The coupling constant H-4/H-3 (J = 7.0 Hz) agreed with a dihedral angle of 30 to 50° or 130 to 150°, indicating two possible orientations for H-4 in a half-chair. Both possible orientations – pseudo-axial or pseudo-equatorial – of H-4 are in accordance with the NOE effect observed between H-4 (δ_{H} 5.43) and H-3 (δ_{H} 3.51). The pseudo-axial orientation of H-4 was finally derived from the ECD spectrum in comparison with the calculated spectrum of compound **2** (see below).

The NMR spectra of compounds **1** and **2** were similar (**Table 1**; **Table 1S**, Supporting Information), the only major difference being in the substituent at C-8 (hydroxyl in **1** and methoxyl in **2**) [16].

The absolute configuration of **2** was established by comparing its experimental ECD spectrum with calculated data of the (3*S*,4*R*)- and (3*S*,4*S*)-diastereomers (**Fig. 4A**). Conformational analysis revealed 68 and 51 conformers, respectively, within a 1 Kcal/mol energy window from the particular global minimum. The conformers were subjected to geometrical optimization DFT and B3LYP level using the 6–31 G** basis set in the gas phase. Vibra-

Fig. 2 Structures of compounds 1–5.

tional analysis was performed to confirm minima. No imaginary frequencies were found. In total, 49 and 30 stable conformers, respectively, were obtained (Fig. 4B; Fig. 14S A, Supporting Information). ECD spectra of the conformers were calculated by TDDFT-B3LYP using 6–31 G** as basis set in MeOH as the solvent and the SCRF method with the CPCM model. For the (3*S*,4*R*)-stereoisomer, the calculated ECD spectrum showed one positive CE around 290 nm along with three negative CEs around 220, 250, and 285 nm (Fig. 4A). For the (3*S*,4*S*)-stereoisomer, the averaged ECD spectrum showed two positive CEs at 290 and 250 nm, and two negative CEs around 220 and 240 nm (Fig. 4A). Even though both spectra were relatively similar, the pattern for the (3*S*,4*R*)-stereoisomer matched well with the experimental ECD spectrum. In particular, the negative CEs at 220, 250, and 285 nm were in very good agreement with the experimental data. We thus concluded that **2** was (3*S*,4*R*)-abruquinone G. The experimental ECD spectrum of **1** was comparable to that of **2**, and we therefore conclude that abruquinone H also has the (3*S*,4*R*)-configuration.

Compound **3** had a molecular formula of C₁₈H₁₈O₇, as derived from HR-ESI-MS (*m/z* 369.0908 [M + Na]⁺; calcd.: 369.0945). The ¹H and ¹³C NMR spectra (Table 1) showed the presence of 18 proton and 18 carbon signals, respectively. Ten carbon signals in the region between δ_C 104.5 and 155.9 were indicative of a highly substituted aromatic ring system. Two resonances at δ_C 178.3 and 186.8 were indicative of conjugated carbonyl groups. The ¹H NMR spectrum (Table 1) showed three singlets for three methoxy groups (δ_H 3.93, 3.83, and 3.77), in agreement with the respective carbon signals at δ_C 61.7, 56.7, and 56.6. Five signals at δ_H 4.43 (dd, *J* = 10.7 and 10.4 Hz), 4.21 (ddd, *J* = 10.7, 3.4, 2.1 Hz), 3.60 (m), 3.12 (dd, *J* = 15.5, 12.3 Hz), and 2.65 (ddd, *J* = 15.5, 4.7, 1.8 Hz) were indicative of an isoflavan scaffold. A comparison of the ¹³C NMR data of ring A with those of laurentiquinone [26] suggested a methoxy group at C-7 and a hydroxy residue at C-8. ¹³C NMR data of ring C were comparable to those of compound **5** (Table 1 and Table 1S). Connectivity of the rings and positions of the methoxy groups were corroborated by HMBC correlations (Fig. 3). ³J_{C–H} correlation between C-9 (δ_C 142.3) and H-5 (δ_H 6.49, ring A) and H-4α and H-4β (δ_H 3.12 and 2.65, ring C) confirmed the connectivity of rings A and C. A correlation between H-3 (δ_H 3.60, ring C) and C-6' (δ_C 131.3, ring B) confirmed the presence of an isoflavan scaffold. Vicinal coupling constants in ring C and NOE difference measurements were used to establish the relative configuration. The vicinal coupling constants H-2α/H-3 (*J* = 3.4 Hz) and H-2β/H-3 (*J* = 10.4 Hz) corresponded to dihedral angles of 60° and 180°, respectively, indicating an axial ori-

Fig. 3 Key HMBC and COSY correlations for compounds 1 and 3.

entation of H-3. The coupling constants H-4α/H-3 (*J* = 12.3 Hz) and H-4β/H-3 (*J* = 4.7 Hz) were in accordance with dihedral angles of 140 to 160° and 40 to 60°, respectively, indicating that H-4α was in a pseudo-axial orientation, and H-4β in a pseudo-equatorial position, respectively [27].

Conformational analysis of **3** displayed 10 conformers within a 1 Kcal/mol energy window from the particular global minimum. Geometrical optimization and energy calculation followed by calculation of ECD spectra were performed as described above. We obtained 9 stable conformers (Fig. 5B; Fig. 14S B, Supporting Information). The calculated ECD spectrum of the (3*R*)-enantiomer showed one positive CE at 206 nm along with two negative CEs around 260 and 320 nm (Fig. 5A). The experimental ECD spectrum showed a positive CE at 212 and a negative CE at 233. The pattern of the calculated ECD spectrum for the (3*R*)-configuration was in good agreement with the experimental ECD spectrum, while the calculated ECD spectra of the (3*S*)-enantiomer (Fig. 5A) showed CEs with opposite signs around 206 and 260 nm. As a result, we concluded that abruquinone I (**3**) had the (3*R*)-configuration.

The absolute configuration of compounds **4** (Figs. 13S A and 14S C, Supporting Information) and **5** (see Figs. 13S B and 14S D, Supporting Information) has been established by comparison of the experimental and calculated ECD spectra as 3*R* and 3*S*, respectively. The absolute configuration of abruquinone B (**4**) had been previously determined by different methods, but reports were contradictory and suggest that both enantiomers may have been isolated from this plant. On the basis of ORD data, a compound was described as (3*S*)-abruquinone [11], and a positive optical rotation was reported [16]. On the other hand, an ECD study assigned the (3*R*)-configuration to the enantiomer exhibiting negative optical rotation [21]. Our ECD data and the sign of optical rotation were in good agreement with [21], which corroborates the

Fig. 4 Comparison of the experimental ECD of **1** and **2** with calculated spectra for the (3S,4R)- and (3S,4S)-diastereomers of **2** (A). DFT optimized conformers at the B3LYP/6–31 G** level in the gas phase (within 1 kcal/mol range from the global minimum) of the (3S,4R)-stereoisomer. Fifty-two conformers grouped in three different core conformers which differed in the alignment of the B ring (B). (Color figure available online only.)

Fig. 5 Comparison of the experimental ECD of **3**, with calculated spectra for the (3S)- and (3R)-enantiomers (A). DFT optimized conformers at the B3LYP/6–31 G** level in the gas phase (within 1 kcal/mol range from the global minimum) of the (3R)-enantiomer. Nine conformers were grouped in three core conformers differing in the alignment of the B ring (B). (Color figure available online only.)

Table 2 *In vitro* antiprotozoal activities of **1–5** against *P. falciparum*, *T. b. rhodesiense*, and *L. donovani*, as well as cytotoxic activity against L-6 cells.

Miltefosine ^e	–	–	–	–	0.285 ± 0.059	–	–
Podophyllotoxin ^e	–	–	–	–	–	–	0.014 ± 0.006

^a Values are expressed as mean ± standard error of the mean; ^b No activity observed at the highest test concentration of 10 μg/mL, which corresponds to molar test concentrations of 24.5 to 28.9 μM; ^c No activity observed at the highest test concentration of 90 μg/mL, which corresponds to molar test concentrations of 260.0 to 220.5 μM; ^d Compound **2** contains about 15% of an unidentified related metabolite; ^e Reference drugs. SI (Selectivity index): Quotient of IC₅₀ in L-6 cells and IC₅₀ against parasite

(3R)-configuration of **4**. As to compound **5** the negative sign of optical rotation agrees with the data reported before for the (3S)-enantiomer prepared by semisynthesis starting from (3S)-duartin [23].

Isoflavonoid hydroquinones **1** and **2** exhibited low activity in both antiprotozoal and cytotoxicity tests (Table 2). In contrast, quinone-type isoflavonoids **3**, **4**, and **5** showed strong activity against *T. b. rhodesiense* (IC₅₀s of 0.3, 0.2, and 0.9 μM, respectively). Compounds **3** and **4** showed low cytotoxicity in the L-6 cell

line (IC₅₀ values of 22.1 and 10.1 µM, respectively). A selectivity index (SI) of 73.7 and 50.5 qualifies the compounds as good candidates for assessment of *in vivo* activity in a murine model [28]. Cytotoxicity of compound **5**, in contrast, was considerably higher (IC₅₀ of 3.9 µM) and resulted in a low SI. We are currently isolating compounds **3** and **4** at a larger scale for an *in vivo* study. There has been so far only one plant-derived natural product, cynaropicrin [8], for which *in vivo* activity against *T. brucei* has been demonstrated. Given that abruquinones **3** and **4** possess a tenfold higher SI than cynaropicrin, these compounds are of considerable interest.

Acknowledgements

The authors would like to thank the Council for Scientific and Industrial Research (CSIR), the Swiss Confederation, and the Department of Science and Technology for financial support under the Swiss South African Joint Research Programme (grant JRP 03), and SANBI for the identification of the plant species. Y. Hata gratefully acknowledges a PhD stipend from the Administrative Department of Science and Technology from Colombia (Colciencias) managed by LASPAU. We thank Dr. O. Potterat for helpful comments and Mrs. M. Rogalski for proofreading the manuscript.

Assays for *in vitro* antiprotozoal activity

Antiplasmodial activity was determined by a modification of the $^3\text{[H]}$ -hypoxanthine incorporation assay [1] with the *P. falciparum* K1 strain (resistant to chloroquine and pyrimethamine), growth according to the method described by Trager and Jensen [2]. Artesunate (purity >95%, Sigma-Aldrich) was used as positive control.

Briefly, a suspension of infected red blood cells (final parasitemia 0.3% and hematocrit 1.25%) in RPMI 1640 medium supplemented with 2 μM L-glutamine, 5.95 g/L Hepes, 2 g/L NaHCO_3 , and 5% of Albumax II was exposed to serial drug dilutions covering a range from 10 $\mu\text{g/mL}$ to 0.156 $\mu\text{g/mL}$ in 96-well microtiter plates. After 48 h of incubation (4% CO_2 , 3% O_2 , and 93% N_2 at 37°C), 50 μL of $^3\text{[H]}$ -hypoxanthine (0.25 μM) were added to each well (Costar). The plates were incubated for further 24 h before being harvested by using a Betaplate cell harvester (Wallac) onto glass-fiber filters and then washed with distilled water. The dried filters were inserted into plastic foils with 10 mL scintillation fluid. The radioactivity was counted with a Betaplate liquid scintillation counter (Wallac) as counts per minute per well at each drug concentration and compared to the untreated controls. Counts were expressed as percentages of the control and presented as sigmoidal inhibition curves. IC_{50} values were calculated by linear interpolation.

Antitrypanosomal activity against *T. brucei rhodesiense* STIB 900 was determined according to [3]. Melarsoprol (Arsorbal, purity >95%, Sanofi-Aventis) was used as positive control. Minimum essential medium (MEM) with Earle's salts supplemented with 2-mercaptoethanol, as described by Baltz *et al.* [4], 1 mM sodium pyruvate, 0.5 mM hypoxanthine, and 15% heat-inactivated horse serum was added (50 μL) to each well of a 96-well microtiter plate (Costar) except of the negative control. Serial drugs dilutions were prepared covering range from 90 to 0.123 $\mu\text{g/mL}$ followed by the parasite suspension of 2000 *T. brucei rhodesiense* STIB 900 bloodstream forms/well. After 70 hours of incubation (humidified 5% CO_2 atmosphere at 37°C), 10 μL resazurin solution (12.5 mg resazurin (Sigma-Aldrich) dissolved in 100 mL of distilled water) were added and incubation was continued for further 2 to 6 h. The plate was read with a Spectramax Gemini XS microplate fluorescence reader (Molecular Devices) with an excitation wavelength of 536 nm and an emission wavelength of 588 nm. Fluorescence development was expressed as percentage of the control and the IC_{50} values were determined from the sigmoid curves using Softmax Pro Software (Molecular Devices).

The assay with *T. cruzi* was performed according to [5], with some modifications. Rat skeletal myoblast cells (L6-cells) were seeded in 96-well microtiter plates (Costar) at 2000 cell/well/100 μ L in RPMI 1640 medium supplemented with 10% fetal bovine serum (FBS) and 2 mM L-glutamine. After 24 h of incubation (humidified 5% CO₂ atmosphere at 37°C, the medium was replaced by 100 μ L of fresh medium containing 5000 trypomastigote forms of *T. cruzi*/well (Tulahuen strain C2C4 containing the β -galactosidase (Lac Z) gene). After 48 h, the medium was removed from the wells and replaced by 100 μ L of fresh medium with the serial drug dilution, covering a range from 90 μ g/mL to 0.123 μ g/mL. After 96 h of incubation 50 μ L chlorophenyl red β -D-galactopyranoside agent (CPRG)/Nonident (Sigma - Aldrich) was added to all wells. The plates were read photometrically at 540 nm [5]. Optical density values were expressed as percentages of control, and IC₅₀ values were calculated from the sigmoid inhibition curve. Benznidazole (purity >95%, Sigma-Aldrich) was used as positive control.

Leishmanicidal activity was determined with *L. donovani* (axenic amastigotes) MHOM-ET/67/L82 strain according to [6], with some modifications. Fifty microlitres of SM medium at pH 5.4 supplemented with 10% heat-inactivated FBS was added to each well of 96-well microtiter plate (Costar). Serial drug dilutions were prepared covering a range from 90 to 0.123 μ g/mL. Then, 10⁵ axenically growth *L. donovani* amastigotes in 50 μ L medium, were added to each well and the plate was incubated for 72 h (humidified 5% CO₂ atmosphere at 37°C). Ten microlitres resazurin solution (12.5 mg resazurin (Sigma-Aldrich) dissolved in 100 mL of distilled water) were added to each well and incubated for further 2 to 4 h. The plate was read with a Spectramax Gemini XS microplate fluorescence reader (Molecular Devices) with an excitation wavelength of 536 nm and an emission wavelength of 588 nm. Fluorescence development was expressed as percentage of the control and the IC₅₀ values were determined from the sigmoid curves using Softmax Pro Software (Molecular Devices). Miltefosine (purity >95%, VWR) was used as positive control.

***In vitro* cytotoxicity assay**

The cytotoxicity assay was performed using a protocol based on the Alamar Blue assay [7], whereby rat skeletal myoblast cells (L-6 cells) were seeded in 96-well microtiter plates using MEM supplemented with 10% heat inactivated FBS (4000 cells/well). Serial threefold drug dilutions ranging from 90 to 0.123 mg/mL were prepared. After 72 h, 10 μ L resazurin

solution was added (12.5 mg resazurin (Sigma-Aldrich) dissolved in 100 mL of distilled water) and the plates were incubated for further 2 to 4 h. A Spectramax Gemini XS micro plate fluorescence reader (Molecular Devices) was used to measure the plates at an excitation wavelength of 536 nm and an emission wavelength of 588 nm. Fluorescence development was expressed as percentage of the control and the IC₅₀ values were determined from the sigmoid curves using Softmax Pro Software (Molecular Devices). Podophyllotoxin (purity >95%, Sigma-Aldrich) was used as a reference drug.

Physicochemical data of **2**, **4** and **5**

(3*S*-4*R*)-4,1',4'-trihydroxy-6,7,8,2',3'-pentamethoxyisoflavan (Abruquinone G, **2**) [8]: White amorphous substance; UV (MeOH): λ_{\max} (log ϵ) = 205 (4.66), 296 (3.88) nm; ¹H and ¹³C NMR data, see Table 1S; HRESI-MS: m/z = 413.1178 [M-H₂O+Na]⁺ (calcd. for C₂₀H₂₄NaO₉: 413.1027).

(3*R*)-6,7,8,2',3'-pentamethoxyisoflavan-1',4'-quinone (Abruquinone B, **4**) [8, 9, 10, 11]: Red-brown amorphous substance; UV (MeOH): λ_{\max} nm (log ϵ) = 203 (4.61), 268 (4.06) nm; ¹H NMR data, see Table 1; ¹³C NMR data, see Table 1; HRESI-MS: m/z = 413.1182 [M+Na]⁺ (calcd. for C₂₀H₂₂NaO₈: 413.1207).

(3*S*)-7,8,3',5'-tetramethoxyisoflavan-1',4'-quinone (**5**) [12]: Orange amorphous substance; UV (MeOH): λ_{\max} (log ϵ) = 205 (4.59) nm, 286 (3.91) nm; ¹H NMR data, see Table 1; ¹³C NMR data, see Table 1; HRESI-MS: m/z = 383.1143 [M+Na]⁺ (calcd. for C₁₉H₂₀NaO₇: 383.1101).

Table 1S. ^1H and ^{13}C NMR data (CD_3OD , 500 MHz for ^1H , 125 MHz for ^{13}C) for compounds **2**, **4**, and **5**.

3.4 Antitrypanosomal Activity of Isoflavan Quinones from *Abrus precatorius*

Yoshie Hata, Samad Nejad Ebrahimi, Maria de Mieri, Stefanie Zimmermann, Tsholofelo Mokoka, Dashnie Naidoo, Gerda Fouche, Vinesh Maharaj, Marcel Kaiser, Reto Brun, Olivier Potterat, Matthias Hamburger

Fitoterapia 93 (2014) 91-87. DOI: 10.1016/j.fitote.2013.12.015

In an attempt to isolate sufficient amounts of abruquinone B and I (at least 30 mg of each one) to perform *in vivo* trypanocidal assays in mice, a second batch of *Abrus precatorius* was recollected. The chemical profiles of batch I and II were compared, and major differences were found. Five abruquinones were isolated as minor compounds, 3 of them resulted to be new compounds. Four of the substances showed high *in vitro* activity against *Trypanosoma brucei rhodesiense* and remarkable selectivity. Even though the initial goal of isolating abruquinones B and I in large amounts could not be accomplished, we isolated new antiprotozoal abruquinones, confirming our findings that these compounds are promising for further *in vivo* evaluation.

My contributions to this work were: (1) large scale separation of the CH₂Cl₂/MeOH (1:1) extract of A. precatorius; (2) isolation of abruquinones; (3) recording and interpretation of analytical data for structure elucidation (HPLC-PDA-ESI-MS, TOF-MS, 1D and 2D NMR, CD measurements) and other measurements such as optical rotation; (4) writing of the draft manuscript, preparation of figures, tables, and supporting information.

Samad Ebrahimi did the quantum-chemical calculation of ECD spectra and, under his supervision I participated in the respective analysis. Maria De Mieri supervised structure elucidation. In vitro antiprotozoal and cytotoxicity tests were performed in the Swiss TPH. The crude extract was provided by the CSIR team.

ABSTRACT

Human African trypanosomiasis is a neglected tropical disease in sub Saharan Africa that is fatal if left untreated. In a search for new natural products with antitrypanosomal activity, we recently identified abruquinones B and I from *Abrus precatorius* as potent *in vitro* trypanocidal compounds with high selectivity indices. To obtain sufficient compound for *in vivo* efficacy tests in mice, a second batch of plant material was re-collected and extracted. However, the chemical profiles of the two batches differed, and additional abruquinones were isolated and identified by HR-ESI-MS, and 1D and 2D NMR (¹H, ¹³C, COSY, HMBC, HSQC, and NOESY) spectroscopy. Abruquinones J (**1**), K (**2**), and L (**3**) were new, while abruquinones A (**4**) and D (**5**) were known from the first batch of plant material. The absolute configuration of compounds **1** to **3** was determined by comparison of electronic circular dichroism (ECD) spectra with calculated ECD data. Compounds **2** to **5** showed high *in vitro* activity against *T. b. rhodesiense* (IC₅₀ of 0.01, 0.02, 0.02 and 0.01 μM, respectively), and remarkable SIs of 508, 374, 1379, and 668, respectively.

1. Introduction

Human African trypanosomiasis (HAT) is a neglected tropical disease caused by two subspecies of *Trypanosoma brucei*. *T. b. gambiense* is endemic in 24 countries of western and central Africa and causes more than 95% of the reported cases of HAT, while *T. b. rhodesiense* is endemic in 13 countries of eastern and southern Africa. Trypanosomiasis mainly affects population located in poor and remote rural regions. The number of infected individuals reported annually is decreasing since the turn of the millennium reaching 7200 reported cases in 2012 while the estimated number of cases is 20,000 to 30,000 [1,2].

Four drugs are currently used for the treatment of HAT, namely pentamidine, suramin, melarsoprol, and eflornithine. However, these drugs suffer from severe limitations, such as (i) lack of oral bioavailability (all of them must be administered parenterally) and chemical stability (suramin rapidly decomposes in air), (ii) complicated and long dose regimens (suramin administration can last up to 30 days) and short half-life (four infusions of eflornithine per day are necessary), and (iii) severe adverse drug reactions (pentamidine is nephrotoxic, and melarsoprol causes a fatal encephalopathy in up to 10% of the treated patients) [2–4]. The need for better drugs is urgent [3,5,6].

Natural products have been a promising source for drugs, especially for treatment of infectious and neglected diseases [4,7,8]. In a medium throughput screening of an extract library of South African medicinal plants with traditional use in protozoan diseases [8–12] the CH₂Cl₂/MeOH (1:1) extract of *Abrus precatorius* L. ssp. *africanus* Verdc had shown *in vitro*

activity against *T. b. rhodesiense*. With the aid of HPLC-based activity profiling we then identified two isoflavan quinones with potent *in vitro* activity and promising selectivity [11]. The two compounds, abruquinones B and I, fulfilled the criteria for progressing to an *in vivo* assessment of their trypanocidal activity. However, the amounts of pure compound available at that time were not sufficient for a preliminary study in mice. Therefore, a second batch of plant material was collected for the purpose of a large scale isolation of abruquinones B and I. This second collection was carried out at the same location as the first one, albeit at a different time of the year (November for the first, and April for the second collection). When comparing the phytochemical profiles of extracts from the first and second collection of *A. precatorius* (batch I and II, respectively) by TLC and HPLC-PDA-MS, we found substantial differences in their chemical composition. Most important, no peaks corresponding to abruquinones B and I were detected in batch II (Fig. 1). Isoflavonoids were found only after enrichment by flash chromatography. Given that the HPLC-PDA-MS data suggested the presence of new isoflavan quinones in these fractions, we proceeded to a targeted isolation of these compounds.

2. Materials and methods

2.1. General experimental procedures

HPLC-grade acetonitrile (MeCN) (Scharlau Chemie S.A.), and water (obtained by an EASY-pure II from Barnstead water

purification system, Dubuque) were used for HPLC separations. HPLC solvents contained 0.1% HCOOH (Sigma) for analytical separations. Chloroform-*d* (100 atom% D) and benzene-*d*₆ (100 atom% D) for NMR were purchased from Armar Chemicals. Solvents used for extraction were of analytical grade (Romil Pure Chemistry). Reference drugs for bioassays were chloroquine (>98%, Sigma-Aldrich), melarsoprol (>95%, Sanofi-Aventis), miltefosine (>95%, VWR), and podophyllotoxin (>95%, Sigma-Aldrich). HPLC-PDA-MS analyses were performed with an Agilent 1100 system consisting of a degasser, a quaternary pump, a column oven, and a PDA detector connected to a Gilson 215 injector and to an Esquire 3000 plus ion trap mass spectrometer (Bruker Daltonics). Data acquisition and processing were done by using HyStar 3.0 software (Bruker Daltonics).

Flash chromatography was carried out with a PuriFlash® 4100 chromatography system (Interchim) controlled by InterSoft V5.0 software. Semi-preparative HPLC was performed with an Agilent 1100 series instrument equipped with a PDA detector. Data acquisition and processing were performed using HyStar 3.2 software (Bruker Daltonics). For HR-ESI-MS a microTOF ESI-MS system (Bruker Daltonics) was used. Mass calibration was performed with a solution of formic acid 0.1% in 2-propanol/water (1:1) containing 5 mM NaOH. Mass spectra were recorded in the range of *m/z* 150–1500 in positive ion mode with the aid of microTOF control software 1.1 (Bruker Daltonics). NMR spectra were recorded on a Bruker AVANCE III™ 500 MHz spectrometer equipped

Fig. 1. HPLC-PDA analysis of batch I and II of *A. precatorius*. For separation conditions, see Section 2.3. Peak letters, in batch I between minutes 13 and 18, refer to the abruquinones isolated from batch I [11]. Abruquinone H (A), abruquinone G (B), abruquinone I (C), abruquinone B (D), and 7,8,3',5'-tetramethoxyisoflavan-1',4'-quinone (E). No peaks are present, in the same time window, in batch II.

with a 1 mm TXI microprobe (^1H and 2D NMR) or a 5 mm BBO probe (^{13}C NMR) (Bruker BioSpin) operating at 500 (^1H) and 125 MHz (^{13}C). Chemical shifts are reported as δ values (ppm) with the residual solvent signal as internal reference, J in Hz. Standard pulse sequences from Topspin 3.0 software package were used. CD spectra were recorded with a ChirascanTM CD Spectrometer, Pro-Data Software V2.4.2 and optical rotation with a Jasco P-2000 polarimeter, equipped with a 1 dm microcell and software Spectra Manager version 2.

2.2. Plant material

Samples of the whole plant of *A. precatorius* (batch II) were collected at Jozini, KwaZulu Natal Province in South Africa during April 2012 by a botanist, Mr. Hans Vahrmeijer. The plant was identified as *Abrus precatorius* L. ssp. *africanus* Verdc, and a herbarium specimen was deposited at the South African National Biodiversity Institute (SANBI) (voucher specimen number PRE 782945).

The whole plant was dried in an oven at 30–60 °C. Dried plant material was ground to a coarse powder using a hammer mill and stored at ambient temperature prior to extraction. One kilogram of dried, ground material was extracted with 5 L of a mixture of CH_2Cl_2 and MeOH (1:1) at room temperature for 1 h with occasional stirring. The solvent was filtered and the residual plant material further extracted overnight with 2.5 L CH_2Cl_2 /MeOH (1:1) followed by filtration. Finally, a third extraction of the pulp was done with 2.5 L solvent for 1 h with filtration. The pulp was discarded and the filtrates combined and concentrated using a rotary vacuum evaporator at a temperature below 45 °C and then further dried *in vacuo* at room temperature for 24 h. The dried extract of 55.0 g (5.5%, w/w) was stored at –20 °C.

2.3. Fractionation and isolation

The CH_2Cl_2 /MeOH (1:1) extract of the whole plant (15 g) was separated by flash chromatography on a silica gel (15–40 μm) column (50 \times 3500 mm, 300 g) by a gradient elution with ethyl acetate (B) in *n*-hexane (A) as follows 0% \rightarrow 40% B (0–3 h), 40% B (1 h), and 40% \rightarrow 100% B (1 h) at a flow rate of 22 mL/min. Fractions (22 mL each) were combined based on TLC analysis. Twenty two fractions were obtained and analyzed by HPLC-PDA-MS on a SunFireTM C18 column (3.5 μm , 3.0 \times 150 mm; Waters) with H_2O (solvent A) and MeCN (solvent B) using the flowing gradient profile: 10% \rightarrow 100% B (0–30 min) and 100% B (31–32 min). The flow rate was 0.5 mL/min. Fractions F12 (19.1 mg), F13 (36.0 mg), F16 (23.4 mg), and F17 (31.1 mg) were found to contain abruquinones (Fig. A1 of Appendix A). These fractions were purified by semi-preparative RP-HPLC using a SunFireTM C18 column (3.5 μm , 10 \times 150 mm, Waters) with H_2O (solvent A) and MeCN (solvent B) and the following gradient 25% \rightarrow 42% B (0–11.1 min), 42% \rightarrow 48% B (11.1–20.9 min), 48% \rightarrow 100% B (20.9–27.2 min), and 100% B (27.2–34.8 min). The flow rate was 4 mL/min. Fractions were dissolved in DMSO (10 or 20 mg/mL, depending on their solubility) and injected in aliquots of 300 μL . Eight compounds were obtained. Compounds **1** to **5** were obtained only from batch II. Compound **1** (5.1 mg, t_R 13.7 min) was isolated from F16 and F17, compound **2** (6.1 mg, t_R 15.2 min) from F17, compound **3** (1.3 mg, t_R 12.6 min) from F13, compound **4** (3.4 mg, t_R 17.9 min) from F13 and compound **5** (3.2 mg, t_R 12.4 min) from F16 and F17. In addition, previously reported [11] abruquinone H (**A**) (2.3 mg, t_R 12.9 min) was obtained from F16 and F17, abruquinone I (**C**) (3.1 mg, t_R 14.9 min) from F13, and 7,8,3',5'-tetramethoxyisoflavan-1',4'-quinone

2.4. Electronic circular dichroism

The absolute configuration (AC) of compounds **1** and **3** was established by electronic circular dichroism (ECD). Experimental ECD spectra were compared with calculated

data, as previously described [11,15,16]. A detailed procedure is given in Appendix A.

2.5. Antiprotozoal and cytotoxicity tests

The *in vitro* antiprotozoal activity of compounds was tested against *Plasmodium falciparum* (K1 strain), *Trypanosoma brucei rhodesiense* (STIB 900 strain), *Trypanosoma cruzi* (Tulahuen strain C2C4 w/LacZ), and *Leishmania donovani* (strain MHOM/ET/67/L82). Cytotoxicity was determined with the rat skeletal myoblast cell line (L-6 cells). For the assays DMSO stock solutions (10 mg/mL) of extracts and purified compounds were freshly diluted in medium prior to testing (final DMSO concentration in assay <1%). Assays were performed in three independent repetitions. Details on culturing of parasites and assay protocols are provided as Appendix A.

3. Results and discussion

The phytochemical profiles of batches I and II were compared by HPLC-PDA-MS (Fig. 1). In the $\text{CH}_2\text{Cl}_2/\text{MeOH}$ (1:1) extract of batch II no abruquinones were detected. After an enrichment by silica gel flash chromatography, isoflavan quinones could be detected, albeit in much lower concentrations than in batch I. Purification of isoflavanoids was achieved by semi-preparative RP-HPLC of selected fractions, and a total of eight compounds were obtained in milligram amounts. Structures were established by NMR spectroscopy (^1H , ^{13}C , COSY, HSQC, and HMBC), HR-ESI-MS and ECD. Compounds **1** [(3S,4S)-4,6,1',2'-tetrahydroxy-7,3'-dimethoxyisoflavan], **2** [(3S,4R)-4,7,1',4'-tetrahydroxy-6,2',3'-trimethoxyisoflavan], and **3** [(3R)-7,1',4'-trihydroxy-6,2',3'-trimethoxyisoflavan] are new natural products and have been designated as abruquinones J, K, and L, respectively (Fig. 2).

For compound **1**, a molecular formula of $\text{C}_{17}\text{H}_{18}\text{O}_7$ was deduced from HR-ESI-MS (m/z 339.0848 $[\text{M}-\text{H}_2\text{O} + \text{Na}]^+$; calculated: 334.1053). The ^{13}C NMR spectrum (Table 1) showed 17 signals, twelve of which were found in the region between δ_C 100.2 and 149.4. This was indicative of a highly substituted aromatic ring system. The remaining carbon resonances were attributed to an oxygenated methine (δ_C 79.6), an oxygenated methylene (δ_C 66.9), two methoxy (δ_C 56.7 and 56.2), and one methine group (δ_C 40.6). The ^1H NMR spectrum (Table 1) displayed signals indicative of four aromatic protons (δ_H 7.09 (s), 6.70 (dd, $J = 8.0, 1.0$ Hz), 6.43 (s) and 6.42 (d, $J = 8.0$ Hz)), and two aromatic methoxy

Fig. 2. Structure of compounds **1–5**.

Fig. 3. Key HMBC and COSY correlations for compounds **1** and **3**.

groups (δ_{H} 3.84 and 3.82). Four aliphatic protons were observed at δ_{H} 5.49 (d, $J = 6.9$ Hz), 3.52 (ddd, $J = 10.8, 6.8, 5.0$ Hz), 3.62 (t, $J = 10.7$ Hz), and 4.19 (dd, $J = 10.8, 4.9$ Hz), suggesting an isoflavan scaffold with a hydroxy group at C-4. Unambiguous assignment of ^1H and ^{13}C NMR data was achieved by a combination of COSY, HMBC, HSQC, and NOESY experiments, and by comparison with reported data of isoflavan quinones and -hydroquinones [11,13,14,17,18]. The connectivity of rings A and C was confirmed by $^3J_{\text{C-H}}$ coupling between H-5 (δ_{H} 7.09, ring A) and C-4 (δ_{C} 79.6, ring C), and HMBC correlations between H-3 (δ_{H} 3.52, ring C) and C-6' (δ_{C} 121.8, ring B), and H-5' (δ_{H} 6.70, ring B) and C-3 (δ_{C} 40.6, ring C) corroborated the connectivity between rings B and C (Fig. 3). The vicinal coupling constants H-2 α /H-3 ($J = 5.0$ Hz) and H-2 β /H-3 ($J = 10.8$ Hz) corresponded to dihedral angles of 60° and 180° , respectively, and indicated an axial orientation of H-3. The coupling constant H-4/H-3 ($J = 6.9$ Hz) agreed with a dihedral angle of 30° to 50° , or 130° to 150° , indicating two possible orientations for H-4 in a half-chair [19]. The NOESY contact observed between H-4 (δ_{H} 5.49) and H-3 (δ_{H} 3.52) did not allow for the unambiguous differentiation between a pseudo-axial or pseudo-equatorial orientation of H-4. The pseudo-equatorial orientation of H-4 was finally deduced from a conformational analysis performed for the calculation of the ECD spectrum of compound **1**. The absolute configuration was established by comparing the experimental ECD spectrum with data calculated for the (3*S*,4*R*) and (3*S*,4*S*) diastereomers (Fig. 4). A total of 8 and 6 conformers, respectively, were found within a 1 Kcal/mol energy window from the particular global minimum (Fig. A24 of Appendix A). The conformers were subjected to geometrical

optimization in the gas phase [20,21], ECD spectra were calculated for each one of them (Fig. A26 of Appendix A), and a final ECD spectrum was obtained after combination of the individuals spectra, according to their population contribution. The calculated ECD spectrum for the (3*S*,4*R*)-stereoisomer showed three negative CEs around 200, 213, and 280 nm, and two positive CEs at 230 and 263 nm (Fig. 4), while the ECD spectrum for the (3*S*,4*S*)-stereoisomer showed a positive CE around 200 nm. Hence, the strong positive CE around 200 nm and the general appearance of the experimental ECD spectrum matched well with the calculated spectrum of the (3*S*,4*S*)-stereoisomer, and compound **1** was thus established as (3*S*,4*S*)-4,6,1',2'-tetrahydroxy-7,3'-dimethoxyisoflavan.

Compound **2** had a molecular formula of $\text{C}_{18}\text{H}_{20}\text{O}_8$, as derived from HR-ESI-MS (m/z 369.1000 $[\text{M}-\text{H}_2\text{O} + \text{Na}]^+$; calculated: 364.1158). The ^{13}C NMR and ^1H NMR spectra (Table 1) showed an additional methoxy group when compared to **1**. Like compound **1**, the ^1H NMR spectrum of **2** showed four aliphatic protons. The COSY and HMBC correlations (Fig. 3) confirmed the presence of an isoflavan scaffold with a hydroxyl group at C-4. A pseudo-axial orientation of H-4 was finally derived from a conformational analysis performed for calculation of the ECD spectrum [11]. Compound **2** showed a strong negative CE around 210 nm, and a weak negative CE at 290 nm (Fig. A23A of Appendix A), similar to (3*S*,4*R*)-abruquinone G [11]. Therefore, the absolute configuration was established as (3*S*,4*R*). Compound **3** had a molecular formula of $\text{C}_{18}\text{H}_{20}\text{O}_7$, as indicated by its HR-ESI-MS (m/z 371.1155 $[\text{M}-\text{H}_2\text{O} + \text{Na}]^+$; calculated: 348.1209). Analysis of the ^{13}C NMR and ^1H NMR spectra (Table 1) showed that **3** was closely related to isoflavanoid **2**,

Fig. 4. Comparison of the experimental ECD of **1** with calculated spectra for the (3*S*,4*R*) and (3*S*,4*S*)-diastereomers.

Fig. 5. Comparison of the experimental ECD of **3**, with calculated spectra for the (3*R*)-enantiomer.

the main difference being the presence of a methylene group (δ_{H} 2.87, δ_{C} 30.5) instead of an oxygenated methine. The COSY and HMBC correlations (Fig. 3) were in agreement with those observed for **2** and confirmed the presence of an isoflavan scaffold. The equatorial orientation of the B-ring was deduced from the vicinal coupling pattern of 3-H (δ_{H} 3.52, ddd $J = 11.0, 9.0, 5.5, 3.5$) that indicated a *trans*-diaxial orientation of H-2_{axial}/H-3 ($J = 11.0$ Hz), and H-3/H-4_{pseudoaxial} ($J = 9.0$ Hz). A conformational analysis of **3** revealed 11 conformers within a 1 Kcal/mol energy window from the particular global minimum (Fig. A25 of Appendix A). The calculated ECD spectrum of the (3*R*)-enantiomer showed a positive CE around 204 nm, and two negative CEs at 212 and 235 nm. This pattern fitted well with the experimental spectrum of **3** (Fig. 5) which showed a strong positive CE at 202 nm and two negative CEs at 212 and 233 nm. Compound **3** was thus (3*R*)-7,1',4'-trihydroxy-6,2',3'-trimethoxyisoflavan.

Isoflavonoids **4** and **5** were identified from their HR-ESI-MS, 1D and 2D NMR data, as abruquinones A [13,14] and D [14], respectively. The AC of both compounds was assessed by ECD (Fig. A23B and A23C of Appendix A). Their experimental spectra were very similar and fitted well with the spectrum of (3*R*)-abruquinone B [11]. Accordingly, **4** and **5** were thus [(3*R*)-6,7,2',3'-tetramethoxyisoflavan-1',4'-quinone] and

[(3*R*)-7-hydroxy-6,2',3'-trimethoxyisoflavan-1',4'-quinone], respectively. The AC of **4** had been reported earlier, but reports were contradictory and suggested that both enantiomers had been found in *A. precatorius* [11,13,14]. In contrast, our findings for **5** were in agreement with the literature [14]. Abruquinone H, I and 7,8,3',5'-tetramethoxyisoflavan-1',4'-quinone had been previously isolated from batch I of *A. precatorius* [11].

Compounds **2** to **5** showed strong *in vitro* activity against *T. b. rhodesiense* (IC₅₀ values of 0.11, 0.02, 0.02, and 0.01 μM , respectively) and low cytotoxicity in L-6 cells (IC₅₀ values of 57.3, 7.5, 34.5, and 4.8 μM , respectively). The selectivity indices (SIs of 508, 374, 1379, and 668) are high enough to warrant *in vivo* tests in mice. In addition, *in vitro* activity against *P. falciparum* and *L. donovani* was assessed (Table 2). However, all compounds showed low or no inhibitory effect at the concentrations tested.

Even though the initial goal of isolating abruquinones B and I for *in vivo* testing was not achieved, we were able to identify a series of new isoflavan quinones with promising *in vitro* activity. This corroborates our earlier findings that these compounds warrant an *in vivo* evaluation in the acute rodent model of *T. b. rhodesiense* [22]. The qualitative and quantitative differences in isoflavonoids between the two batches appear to be a seasonal effect given that the material was collected in the same location, but at different times of the

Assays for *in vitro* antiprotozoal activity

Antiplasmodial activity was determined by a modification of the $^3\text{[H]}$ -hypoxanthine incorporation assay [1] with the *P. falciparum* K1 strain (resistant to chloroquine and pyrimethamine), growth according to the method described by Trager and Jensen [2]. Artesunate (purity >95%, Sigma-Aldrich) was used as positive control.

Briefly, a suspension of infected red blood cells (final parasitemia 0.3% and hematocrit 1.25%) in RPMI 1640 medium supplemented with 2 μM L-glutamine, 5.95 g/L Hepes, 2 g/L NaHCO_3 , and 5% of Albumax II was exposed to serial drug dilutions covering a range from 10 $\mu\text{g/mL}$ to 0.156 $\mu\text{g/mL}$ in 96-well microtiter plates. After 48 h of incubation (4% CO_2 , 3% O_2 , and 93% N_2 at 37°C), 50 μL of $^3\text{[H]}$ -hypoxanthine (0.25 μM) were added to each well (Costar). The plates were incubated for further 24 h before being harvested by using a Betaplate cell harvester (Wallac) onto glass-fiber filters and then washed with distilled water. The dried filters were inserted into plastic foils with 10 mL scintillation fluid. The radioactivity was counted with a Betaplate liquid scintillation counter (Wallac) as counts per minute per well at each drug concentration and compared to the untreated controls. Counts were expressed as percentages of the control and presented as sigmoidal inhibition curves. IC_{50} values were calculated by linear interpolation.

Antitrypanosomal activity against *Trypanosoma brucei rhodesiense* STIB 900 was determined according to [3]. Melarsoprol (Arsorbal, purity >95%, Sanofi-Aventis) was used as positive control. Minimum essential medium (MEM) with Earle's salts supplemented with 2-mercaptoethanol, as described by Baltz *et al.* [4], 1 mM sodium pyruvate, 0.5 mM hypoxanthine, and 15% heat-inactivated horse serum was added (50 μL) to each well of a 96-well microtiter plate (Costar) except of the negative control. Serial drugs dilutions were prepared covering a range from 90 to 0.123 $\mu\text{g/mL}$ followed by the addition of 2000 *T. brucei rhodesiense* STIB 900 bloodstream forms/well. After 70 hours of incubation (humidified 5% CO_2 atmosphere at 37°C), 10 μL resazurin solution (12.5 mg resazurin (Sigma-Aldrich) dissolved in 100 mL of distilled water) were added and incubation was continued for further 2 to 6 h. The plate was read with a Spectramax Gemini XS microplate fluorescence reader (Molecular Devices) with an excitation wavelength of 536 nm and an emission wavelength of 588 nm. Fluorescence development was expressed as percentage of the control and the IC_{50} values were determined from the sigmoid curves using Softmax Pro Software (Molecular Devices).

Leishmanicidal activity was determined with *L. donovani* (axenic amastigotes) MHOM-ET/67/L82 strain according to [6], with some modifications. Fifty microlitres of SM medium at pH 5.4 supplemented with 10% heat-inactivated FBS was added to each well of 96-well microtiter plate (Costar). Serial drug dilutions were prepared covering a range from 90 to 0.123 $\mu\text{g/mL}$. Then, 10^5 axenically grown *L. donovani* amastigotes in 50 μL medium were added to each well and the plate was incubated for 72 h (humidified 5% CO_2 atmosphere at 37°C). Ten microlitres resazurin solution (12.5 mg resazurin (Sigma-Aldrich) dissolved in 100 mL of distilled water) were added to each well and incubated for further 2 to 4 h. The plate was read with a Spectramax Gemini XS microplate fluorescence reader (Molecular Devices) with an excitation wavelength of 536 nm and an emission wavelength of 588 nm. Fluorescence development was expressed as percentage of the control and the IC_{50} values were determined from the sigmoid curves using Softmax Pro Software (Molecular Devices). Miltefosine (purity >95%, VWR) was used as positive control.

***In vitro* cytotoxicity assay**

The cytotoxicity assay was performed using a protocol based on the Alamar Blue assay [7], whereby rat skeletal myoblast cells (L-6 cells) were seeded in 96-well microtiter plates using MEM supplemented with 10% heat inactivated FBS (4000 cells/well). Serial threefold drug dilutions ranging from 90 to 0.123 mg/mL were prepared. After 72 h, 10 μL resazurin solution was added (12.5 mg resazurin (Sigma-Aldrich) dissolved in 100 mL of distilled water) and the plates were incubated for further 2 to 4 h. A Spectramax Gemini XS micro plate fluorescence reader (Molecular Devices) was used to measure the plates at an excitation wavelength of 536 nm and an emission wavelength of 588 nm. Fluorescence development was expressed as percentage of the control and the IC_{50} values were determined from the sigmoid inhibition curves using Softmax Pro Software (Molecular Devices). Podophyllotoxin (purity >95%, Sigma-Aldrich) was used as a reference drug.

Calculation of electronic circular dichroism (ECD) spectra

Conformational analysis of **1**, **2**, and **3** was accomplished with Schrödinger MacroModel 9.1 software employing the OPLS 2005 (optimized potential for liquid simulations) force field in H_2O . Conformers within a 1 Kcal/mol energy window from the global minimum were picked for geometrical optimization and energy calculation applying density functional theory (DFT)

with the Becke's nonlocal three parameter exchange and correlation functional, and the Lee-Yang-Parr correlation functional level (B3LYP, Becke, 3-parameter, Lee-Yang-Parr) using the 6-31G** basis set in the gas phase with the Gaussian 09 program package [8]. Vibrational evaluation was done at the same level to confirm minima. Excitation energy (denoted by wavelength in nm), rotator strength dipole velocity (Rvel), and dipole length (Rlen) were calculated in MeOH by TD-DFT/B3LYP/6-31G**, using self-consistent reaction field (SCRF) method, with the conductor polarized continuum model (CPCM) model. ECD curves were obtained on the basis of rotator strengths using a half-band of 0.2 eV using SpecDis v1.51 [9]. The spectra were combined after Boltzmann weighting according to their population contribution.

Physicochemical data of **4** and **5**

(3*R*)-6,7,2',3'-Tetramethoxyisoflavan-1',4'-quinone (Abruquinone A, **4**) [10]: Orange amorphous substance; UV (MeOH): λ_{\max} (log ϵ) = 200 (4.57), 268 (3.91) nm; ^1H and ^{13}C NMR data, see Table 1S; HRESI-MS: m/z = 383.1135 $[\text{M}+\text{Na}]^+$ (calcd. for $\text{C}_{19}\text{H}_{20}\text{O}_7$: 360.1209).

Phytochemistry letters. Accepted.

HPLC-based activity profiling allowed the identification of a new phenanthrenone from the stems extract of *Drypetes gerrardii*. Alongside, its dimer could be isolated. Both compounds showed activity against *Plasmodium falciparum*. However, the phenanthrenone exhibited more potency and selectivity than the dimer. As a result, the phenanthrenone was isolated in large scale for *in vivo* assessment. Interestingly, the compound turned out to be inactive. Furthermore, a saponin with weak trypanocidal activity, putranoside A, could be isolated from the leaves extract after being localized by the aid of a HPLC-based activity profiling.

My contributions to this work were: (1) HPLC microfractionation of the CH₂Cl₂/MeOH (1:1) extract of Drypetes gerrardii (stems); (2) isolation of a phenanthrenone and its dimer, (3) recording and interpretation of analytical data for structure elucidation (HPLC-PDA-ESI-MS, TOF-MS, 1D and 2D NMR); (4) large scale isolation of the phenanthrenone for in vivo antimalarial test; (5) HPLC microfractionation of the CH₂Cl₂/MeOH (1:1) extract of D. gerrardii (leaves); (6) isolation of a saponin, hydrolysis, recording and interpretation of analytical data for structure elucidation (HPLC-PDA-ESI-MS, TOF-MS, 1D and 2D NMR), data analysis, (7) writing of the manuscript draft, preparation of figures, tables, and supporting information.

Maria de Mieri supported the structure elucidation of the phenanthrenones and wrote the corresponding results section in the paper. Melanie Raith supervised the saponin structure elucidation. In vitro antiprotozoal and cytotoxicity tests were performed at the Swiss TPH. The crude extracts were provided by the CSIR team.

Abstract

In an *in vitro* screen of 206 extracts from South African plants, the CH₂Cl₂/MeOH (1:1) stem extract of *Drypetes gerrardii* Hutch. var *gerrardii* (Putranjivaceae) inhibited *Plasmodium falciparum* and *Leishmania donovani* (IC₅₀s of 0.50 and 7.31 µg/ml, respectively). In addition, the CH₂Cl₂/MeOH (1:1) extract of the leaves showed activity against *Trypanosoma brucei rhodesiense* (IC₅₀ of 12.1 µg/ml). The active constituents were tracked by HPLC-based activity profiling, and isolated by preparative and semi-preparative RP-HPLC chromatography. Their structures were established by HRESIMS, and 1D and 2D NMR (¹H, ¹³C, COSY, HMBC, HSQC, and NOESY). From the stem extract, a new phenanthrenone derivative, drypetenone D (**1**), and a phenanthrenone heterodimer, drypetenone E (**2**), were isolated. Compound **1** showed potent *in vitro* activity against *P. falciparum* (IC₅₀ of 0.9 µM) with a selectivity index (SI) of 71, as calculated from cytotoxicity data for L-6 cells. These data qualified **1** for *in vivo* assessment in the *Plasmodium berghei* mouse model, but the compound turned out to be inactive. Compound **2** also exhibited good *in vitro* antiplasmodial activity (IC₅₀ of 2.0 µM) and selectivity (SI 31). From the leaf extract, the saponin putranoside A (**3**) was isolated and identified. Compound **3** showed weak *in vitro* trypanocidal activity, with an IC₅₀ of 18.0 µM, and a SI of 4.

Keywords: Antiprotozoal, *Drypetes gerrardii*, Putranjivaceae, phenanthrenones, HPLC-based activity profiling.

1. Introduction

Tropical parasitic diseases have devastating social and economic effects for Third World countries (Renslo and McKerrow, 2006). According to WHO estimations, 207 million cases of malaria infections and 627000 malaria deaths occurred worldwide in 2012. Malaria is transmitted by mosquitoes of the genus *Anopheles* and caused by five *Plasmodium* species. Artemisinin derivatives are the most recent drugs, but artemisinin-resistant *P. falciparum* strains have already emerged in Asia (Miller et al., 2013; WHO, 2013). Human African trypanosomiasis (HAT) is confined to sub-Saharan African countries where tsetse flies (genus *Glossina*) transmit the disease. The number of reported cases was 7197 in 2012. *Trypanosoma brucei gambiense* accounts for more than 98% of the reported cases of HAT and *T. b. rhodesiense* for the rest. Drugs in current use show varying degrees of toxicity and efficacy, and all require parenteral administration (WHO, June, 2013; Brun et al., 2011). There are more than 21 species of *Leishmania* sp. that cause various forms of leishmaniasis ranging from the cutaneous form to the lethal, if untreated, visceral form (VL). VL has an estimated global incidence of 200000 – 500000 cases and a prevalence of 5 million cases worldwide. Antileishmanial drugs are available, but suffer from limited efficacy, long treatments, or high costs (Stuart et al., 2008; WHO, 2010). In view of the unsatisfactory therapeutic options currently available, there is an urgent need for new drugs to treat these diseases (Renslo and McKerrow, 2006; Stuart et al., 2008).

Natural products constitute an invaluable source of new drug scaffolds, particularly in the area of infectious diseases (Hannaert, 2011; Renslo, 2013). In the search for new antiprotozoal compounds, we screened a library of South African medicinal plants for antiprotozoal activity (Hata et al., 2013; Hata et al., 2011; Mokoka et al., 2011; Mokoka et al., 2013). A stem extract from *Drypetes gerrardii* Hutch. var. *gerrardii* (Putranjivaceae) showed pronounced antiplasmodial and antileishmanial activities. In addition, a leaf extract of the same plant

exhibited trypanocidal properties (Mokoka et al., 2013). There are few reports about the phytochemistry of *D. gerrardii*. So far, triterpenes belonging to the friedelane, hopane and lupane series, and flavone dimers, amentoflavone and drypetdimer A, have been isolated (Ng'ang'a et al., 2008; Ng'ang'a et al., 2011). The antiplasmodial activity of the dimeric flavonoids was evaluated against the K1 strain of *P. falciparum* (Ng'ang'a et al., 2012). We report here on the identification of the antiprotozoal constituents from stem and leaf extracts, and on the biological assessment of the isolated compounds.

2. Results and discussion

The CH₂Cl₂/MeOH 1:1 extract of the stems of *D. gerrardii* inhibited *P. falciparum* and *L. donovani* with IC₅₀ values of 0.50 µg/ml and 7.31 µg/ml, respectively. Activity in the extract was tracked by HPLC-based activity profiling (**Fig. 1**). The chromatogram exhibited a strong UV-absorbing peak at *t_r* = 19.0 min which correlated with 71% inhibition of *L. donovani*, and 95% inhibition of *P. falciparum*. The compound was isolated by flash chromatography of the CH₂Cl₂/MeOH (1:1) extract, followed by semi-preparative RP-HPLC. In addition, a structurally related compound **2** was obtained. The structures of **1** and **2** were determined by HRESIMS and NMR analyses (¹H NMR, ¹³C NMR, HMBC, HSQC, and NOESY). Compound **1** had a molecular formula of C₁₇H₁₆O₂ (HRESIMS *m/z* = 275.1067 [M+Na]⁺ (calcd. for C₁₇H₁₆NaO₂, 275.1043), thus requiring 10 degrees of indices of hydrogen deficiency. The ¹H and ¹³C NMR spectra displayed resonances in the low field region of the spectrum and were indicative of a highly substituted aromatic ring system. The ¹H NMR spectrum in CDCl₃ displayed an AX olefinic spin system at δ_H 8.20 (d, *J* = 10.1 Hz) and 6.29 (d, *J* = 10.1 Hz), two *ortho* coupled aromatic protons at δ_H 7.75 (d, *J* = 8.5 Hz) and 7.39 (d, *J* = 8.5 Hz), two aromatic protons as singlets at δ_H 7.59 and 7.53, an aliphatic geminal dimethyl group δ_H 1.51 (6H, s), and an aromatic methyl group at δ_H 2.42. The ¹³C NMR spectrum

displayed seventeen signals consistent with three methyls, six methines, eight quaternary carbons including a carbonyl (δ_C 205.5), one oxygenated aromatic carbon (δ_C 154.7) and a quaternary carbon bearing the *gem*-dimethyl group (δ_C 48.1). A careful analysis of HMBC and NOESY correlations (**Fig. 4**) suggested that **1** possessed a phenanthrenone skeleton similar to trigohowilol A (**4**) (Tang et al., 2012) except for the absence of the hydroxyl group at C-9 and of the *O*-methyl substituent at C-6 in **1**. The location of the scalar coupled doublets (δ_H 7.75 and 7.39, $J = 8.5$ Hz) at positions C-9 and C-10, respectively, was inferred from HMBC correlations from H-9 to C-8, C-4b and C-10a, and from H-10 to C-4a and C-8a. This structural assignment was corroborated by a NOESY correlation between H-9 and H-8, and between H-10 and the *gem*-dimethyl group at C-1. Thus, the structure of **1** was established as shown in **Fig. 3** and the compound was named drypetenone D.

The molecular formula of compound **2** was determined as $C_{34}H_{30}O_4$ (HRESIMS $m/z = 525.2063$ $[M+Na]^+$ (calcd. for $C_{34}H_{30}NaO_4$, 525.2036), with 20 indices of hydrogen deficiency. The 1H and ^{13}C spectra showed the presence of two sets of signals resembling those found for compound **1**, thus suggesting a heterodimeric structure for **2**. The 1H NMR spectrum displayed the resonances of: (1) two *gem*-dimethyl groups, Me-1 (δ_H 1.43, s) and Me-1' (δ_H 1.45, s); (2) two aromatic methyl groups CH_3 -7 (δ_H 2.76, s), CH_3 -7' (δ_H 2.51, s); (3) two sets of AX olefinic doublets H-3 (δ_H 6.03) and H-3' (δ_H 5.96), H-4 (δ_H 7.40) and H-4' (δ_H 8.70); (4) two sets of *ortho* coupled aromatic protons H-9 (δ_H 7.78) and H-9' (δ_H 7.88), H-10 (δ_H 7.43) and H-10' (δ_H 7.49); (5) three uncoupled aromatic protons H-5 (δ_H 6.93), H-8 (δ_H 7.77) and H-8' (δ_H 7.66).

The ^{13}C NMR spectrum showed the signals for the aforementioned protonated carbons (see **Table 1**) and additionally: (1) two carbonyl C-atoms resonating at δ_C 204.5 (C-2) and δ_C 203.9 (C-2'); (2) three oxygen bearing aromatic carbons δ_C 154.6 (C-6), δ_C 147.7 (C-6') and δ_C 134.2 (C-5'); (3) two aliphatic quaternary carbons δ_C 48.0 (C-1), δ_C 48.6 (C-1'); (4) ten

aromatic quaternary carbons δ_C 122.2 (C-4a) and δ_C 121.7 (C-4a'), 130.3 (C-4b) and δ_C 123.5 (C-4b'), 127.0 (C-7) and δ_C 127.6 (C-7'), 129.0 (C-8a) and δ_C 128.7 (C-8a'), 147.5 (C-10a) and δ_C 149.2 (C-10a'). Based on HMBC and NOESY correlations the two substructures A and B (**Fig. 5**) were identified. Substructure A corresponded to compound **1**, while in substructure B position C-5' was hydroxylated. In substructure B, the substitution of the aromatic C ring unit was established on the basis of the NOESY correlations between H-8' and H-9' and between H-8' and CH₃-7'. The positions C-6' (δ_C 147.7) and C-5' (134.2) of ring C were oxygenated; C-6' chemical shift was assigned to be δ_C 147.7 by the $^3J_{H-C}$ HMBC correlation from 7'-CH₃ while the remaining upfield shifted ^{13}C resonance was assigned to position C-5'. Considering the substituents of the substructures A and B it became obvious that they were connected through an ether linkage between position C-6 of substructure A and positions C-5' or C-6' of substructure B. Unfortunately, no cross peaks were detected in the HMBC spectrum from H-5 to substructure B. In a further effort to discriminate between the two possible regioisomers, a long-range optimized (4 Hz) HMBC spectrum was measured. No correlations between the C rings of the two substructures were detected. However, position C-5' could be unequivocally assigned by the $^4J_{H-C}$ HMBC observed with H-9' and H-8'. It was identified as the point of attachment of the ether linkage on substructure B considering the diagnostic upfield shift of δ_C C-5' (δ_C 134.2), with respect to C-6' (δ_C 147.7). A further support to this structure assignment came from the NOESY spectrum that showed a strong dipolar coupling between CH₃-7 (δ_H 2.76) and H-4' (δ_H 8.70). On the basis of these data the structure of **2** was assigned as reported in **Fig. 3** and the new compound named drypetenone E.

A conformational analysis of **2** was performed, followed by geometrical optimization for the conformers found within 1 Kcal/mol from the corresponding global minimum energy. Two iso-energetic conformers were found (**Fig. 6**). DFT-optimized structures showed that the two substructures A and B were almost perpendicular and the distance between CH₃-7 and H-4'

was 3.45 Å for both conformers, thus matching the observed dipolar coupling. The tridimensional rearrangement of drypetenone E (**2**) could also provide an explanation of the significant differences in the ^1H chemical shift between drypetenone D (**1**) and substructure A of **2**.

There are few reports of naturally occurring phenanthrenones. Such compounds have been isolated from a marine bacterium, *Pseudomonas stutzeri* (Uzair et al., 2008), and from terrestrial plants of the genera *Strophoblachia* (Seephonkai et al., 2013a, b; Seephonkai et al., 2009) and *Trigonostemon* (Hu et al., 2009; Kokpol et al., 1990; Tang et al., 2012; Zhu et al., 2010), which belong to the Euphorbiaceae family. Interestingly, the genus *Drypetes* was formerly included in this family.

Compound **1** showed low *in vitro* activity against *L. donovani* (**Table 2**). In contrast, **1** remarkably inhibited *P. falciparum* (IC_{50} of 0.96 μM) and displayed low cytotoxicity for the L-6 cell line (IC_{50} of 68 μM). The selectivity index (SI) calculated as the quotient of IC_{50} for L-6 cells and IC_{50} against parasites gave a value of 71. Compound **2** displayed good *in vitro* activity against *P. falciparum* (IC_{50} of 2.0 μM), even though the selectivity ($\text{SI} = 31$) was not as high as the one of **1**. The low yield of the compound probably explains that its activity was not detected in the HPLC-based activity profiling. These results granted *in vivo* assessment of the antimalarial efficacy of **1** in a mouse model. The full suppressive four-day test was performed on female NMRI mice infected with a GFP-transfected *P. berghei* strain ANKA. Animals treated with compound **1** showed no parasitemia reduction on day 4 compared to untreated control mice. The absence of activity in this model can be due either to absorption problems or unfavourable PK.

Molecular properties associated with drug-likeness and toxicity are essential in early compound selection. Descriptors, such as Lipinski's "rule of 5" (molecular weight, log P, sum of H-donors/acceptors), rotatable bonds, and polar surface area (PSA) can predict drug-

likeness. Compound **1** had a molecular weight of 252 Da, log P of 3.96, sum of H-donors/acceptors of 2, 0 rotatable bonds and a PSA of 37.3 Å², as calculated by Molinspiration Cheminformatics software (Cheminformatics, 2014). All these values fulfil established drug-likeness criteria (Lipinski and Hopkins, 2004; Pajouhesh and Lenz, 2005). Accordingly, oral absorption and blood-brain barrier permeability can be expected for compound **1**. Oral availability is a desired characteristic for an ideal antimalarial drug (Fidock et al., 2004) while blood-brain barrier permeability is prerequisite for an advanced HAT infection (Brun et al., 2011).

An early *in silico* toxicity prediction can help to anticipate potential “off-target” activity. There are a series of proteins involved in development of adverse effects. When the ability of a compound to bind to these proteins is simulated and quantified *in silico*, it is possible to obtain an estimated toxic potential (TP). By using the virtual technology “Virtual ToxLab” we estimated a TP of endocrine and/or metabolic disruption, carcinogenicity, and cardiotoxicity (Vedani et al., 2012). Binding affinities of **1** toward 16 target proteins, were calculated to obtain a TP of 0.52. This TP value categorizes **1** as a class I compound (in a scale of 0 to IV, being IV the most toxic). The binding affinity to critical proteins such as hERG, a potassium ion channel related with cardiotoxicity (IC₅₀ of 40.2 µM), was low. Nevertheless, **1** bound the progesterone receptor with high affinity (IC₅₀ of 46.8 nM). In case the compound progresses through the drug discovery pipeline, this aspect would require further attention since this receptor has a fundamental role during pregnancy and antimalarial drugs are expected to be administered also to pregnant women (Fidock et al., 2004).

The second active extract, the CH₂Cl₂/MeOH 1:1 leaf extract, showed inhibition against *T. b. rhodesiense* with an IC₅₀ of 12.1 µg/ml. HPLC-based activity profiling revealed strong inhibition in the time window of 19 – 20 min which matched with an intense peak in the HPLC-ELSD chromatogram (**Fig. 2**). Targeted isolation of this compound by a combination

of flash chromatography and open column chromatography afforded **3**. Acid hydrolysis afforded two sugar moieties which were identified by GC-MS analysis after derivatization with cysteine methyl ester and silylation (Severi et al., 2010) as L-rhamnose and D-glucuronic acid. The compound was identified by means of HRESIMS, extensive NMR analyses (^1H NMR, ^{13}C NMR, HMBC, HSQC, and NOESY) and comparison with literature data as 3-*O*-[α -L-rhamnopyranosyl-(1 \rightarrow 3)- β -D-glucopyranosyl] oleanolic acid, known as putranoside A (**Fig. 3**) (Borel and Hostettmann, 1987; Hariharan, 1973, 1974; Melek et al., 2003). Compound **3** showed weak *in vitro* trypanocidal (IC_{50} of 18.0 μM) and antileishmanial activities (IC_{50} of 7.8 μM).

It is noteworthy that the antiplasmodial triterpenoids which were previously reported from the leaves and stems of *D. gerrardii*, including the most active lupane-type derivative resinone (IC_{50} of 0.09 mg/ml, SI 942) (Ng'ang'a et al., 2012; Ng'ang'a et al., 2011), were not detected by HPLC-MS analysis in the course of our study.

3. Materials and Methods

3.1 General experimental procedures

HPLC-grade methanol (MeOH), acetonitrile (MeCN) (Scharlau Chemie S.A.), and water (obtained by an EASY-pure II from Barnstead water purification system, Dubuque) were used for HPLC separations. HPLC solvents contained 0.1% HCO_2H (Sigma) for analytical separations. CDCl_3 (100 atom% D), $\text{DMSO}-d_6$ (100 atom% D), and pyridine- d_5 (100 atom% D) for NMR were purchased from Armar Chemicals (Switzerland). Solvents used for extraction were of analytical grade (Romil Pure Chemistry). Reference drugs for bioassays

were chloroquine (>98%, Sigma-Aldrich), melarsoprol (purity >95%, Sanofi-Aventis), miltefosine (purity >95%, VWR), and podophyllotoxin (purity >95%, Sigma-Aldrich). HPLC-PDA-MS analyses were performed on an Agilent 1100 system consisting of a degasser, a quaternary pump, a column oven, a PDA detector and to an Esquire 3000 plus ion trap mass spectrometer (Bruker Daltonics). Data acquisition and processing were performed using HyStar 3.0 software (Bruker Daltonics). HPLC-PDA-ELSD analyses were carried out on an Alliance 2695 HPLC system (Waters) equipped with a 996 PDA (Waters) and an Alltech 2000ES ELSD. ELSD parameters were set as follows: N₂ flow = 3.2 l/min, temp. = 115°C, gain = 8, impactor = off. Empower Pro software (Waters) was used to acquire and process data. Sugar analysis of compound **3** was performed with a HP 5890 Series II gas chromatograph equipped with a HP 5971 mass detector. He was used as a carrier gas. Flash chromatography was carried out on a chromatography system PuriFlash[®] 4100 (Interchim), controlled with InterSoft V5.0 software. Semi-preparative HPLC was performed on an Agilent 1100 series instrument equipped with a PDA detector. Data acquisition and processing were carried out using HyStar 3.2 software (Bruker Daltonics). For HRESIMS a micrOTOF ESI-MS system (Bruker Daltonics) was used. Mass calibration was performed with a solution of formic acid 0.1% in 2-PrOH/H₂O (1:1) containing 5mM NaOH. Mass spectra were recorded in the range of m/z 150 – 1500 in positive ion mode with the aid of micrOTOF control software 1.1 (Bruker Daltonics). NMR spectra were recorded at 18 °C on a Bruker AVANCE IIITM 500 MHz spectrometer operating at 500.13 (¹H) and 125.77 MHz equipped with a 1 mm TXI microprobe (¹H and 2D NMR) or a 5 mm BBO probe (¹³C NMR) (Bruker BioSpin). The ¹³C spectrum of **2** was recorded on a Bruker AscendTM III 600 MHz spectrometer equipped with a QCI cryoprobe. Chemical shifts are reported as δ values (ppm) with the residual solvent signal as internal reference, J in Hz. Standard pulse sequences from Topspin 3.0 software package were used.

3.2 Plant material

Samples of the stems of *D. gerrardii* were collected at Hlatikulu Forest on top of the Lebombo mountains in Gwalewemi, KwaZulu Natal Province in South Africa in April 2012 by a botanist, Mr. Hans Vahrmeijer. A plant specimen was deposited at the South African National Biodiversity Institute (SANBI), and the plant identified as *Drypetes gerrardii* Hutch. var. *gerrardii* (Putranjivaceae) (voucher specimen number PRE 45954).

3.3 Extraction

Stems and leaves were collected, separated and dried separately in an oven at 30-60°C. Dried plant material was ground to a coarse powder using a hammer mill, and stored at ambient temp. prior to extraction. 800 g of dried, ground stems were extracted with 4 l of a mixture of CH₂Cl₂ and MeOH (1:1) at room temp. for 1 h with occasional stirring. The extract was filtered, and the residual plant material further extracted overnight with 2 l CH₂Cl₂/MeOH (1:1), followed by filtration. Finally, a third extraction of the pulp was carried out with 2 l solvent for 1 h with filtration. The filtrates were combined and concentrated using a rotary vacuum evaporator at a temp. below 45°C, and the residue dried *in vacuo* at room temp. for 24 h. The dried extract of 35.0 g (4.4%, w/w) was stored at -20°C. The dried, ground leaves (115 g) of the plant were extracted in a similar way as described above to yield 6.31 g (5.5%, w/w) of extract.

3.4 Microfractionation and activity profiling

HPLC-based activity profiling was performed on a SunFire™ C18 column (3.5 µm, 3.0 × 150 mm, Waters) equipped with a precolumn (3 x 10 mm) as previously described (Adams et al., 2009). H₂O (solvent A) and MeCN (solvent B) were used as solvents, and the following gradient was applied: 10% → 100% B in 30 min, then 100% B for 1 min. The flow rate was 0.5 ml/min. Aliquots (35 µl) of extracts (10 mg/ml in DMSO) were injected, and 32

one-minute fractions collected into a 96 deep well plate (Eppendorf) with the aid of a F204 fraction collector (Gilson). After solvent removal in an Evaporex 96 channel N₂-evaporator (Apricot Designs), the dried fractions were re-dissolved in methanol (100 µl) and transferred to 96 v-well plates (Thermo Scientific), dried again, and stored in a refrigerator (2 – 8°C) until use for bioassay.

3.5 Preparative isolation

The CH₂Cl₂/MeOH (1:1) stem extract of *D. gerrardii* (3.4 g) was fractionated by flash chromatography on a silica gel 60 column (15 – 40 µM, 35 x 430 mm, 180 g) with a gradient of 100-0% hexane in EtOAc in 3 h, using a flow rate of 40 ml/min. Fractions (22 ml each) were collected and compared by TLC analysis [silica gel; hexane/EtOAc (9:1 and 7:3); anisaldehyde/sulphuric acid spraying reagent, heated at 110°C]. Fractions 10 (121.4 mg) and 11 (34.8 mg) were found to contain phenanthrenones. They were purified by semi-preparative RP-HPLC using a SunFire™ C18 column (3.5 µM, 10 x 150 mm; Waters) equipped with a precolumn (10 x 10 mm). H₂O (Solvent A) and MeCN (Solvent B) were used as solvents and the following gradient was applied: 40% → 60% B in 5 min, then 60% → 70% B in 25 min. The flow rate was 4 ml/min. The fractions were dissolved in DMSO (Fr.10: 10 mg/ml; Fr. 11: 20 mg/ml) and injected in aliquots of 300 µl. Compound **1** (24.8 mg, *t_R* 7.7 min) was isolated from Fr. 10 and Fr. 11. Compound **2** (1.4 mg, *t_R* 24.0 min) was obtained from Fr. 10.

The CH₂Cl₂/MeOH (1:1) leaf extract (355 mg) was separated by flash chromatography on a Sepacore® system system (Büchi) by using a pre-packed silica gel 60 cartridge (40 - 63 µm, 40 x 150 mm) with a gradient of 0 - 60% EtOAc in MeOH, over 2 h. The flow rate was 15 ml/min. Fractions (20 ml; each) were combined based on TLC analysis [silica gel; CHCl₃/MeOH/H₂O (65:30:5); vanillin/sulphuric acid reagent, heated at 110°C]. Similar fractions were pooled into four fractions (Fr. A - D). Fr. B (148.7 mg) was further purified by

CC on silica gel (40 - 63 μ m, 8 x 160 mm, 12.1 g) using a step gradient of CHCl₃ and MeOH (100:0, 95:5, 92.5:7.5, 90:10 87.5:12.5, 85:15, 80:20, 70:30, 60:40, 50:50; 50 ml each) to yield 9 sub-fractions (Fr. B₁ - B₉). Subfraction Fr. B₄ eluted with CHCl₃/MeOH (80:20) afforded pure compound **3** (31.3 mg).

Purity of compounds **1** and **3** was > 95%, and that of **2** > 90%, as determined by ¹H NMR (Figs. 1S, 5S, 9S, and 15S of Supplementary content).

6-Hydroxy-1,1,7-trimethylphenanthren-2(1*H*)-one (drypetenone D, **1**): Yellow amorphous substance; ¹H and ¹³C NMR data in CDCl₃ and DMSO-*d*₆, see **Table 1**; HRESIMS: *m/z* = 275.1067 [M+Na]⁺ (calcd. for C₁₇H₁₆Na O₂, 275.1043).

6-Hydroxy-1,1,7-trimethyl-5-((2,8,8-trimethyl-7-oxo-7,8-dihydrophenanthren-3-yl)oxy)phenanthren-2(1*H*)-one (drypetenone E, **2**): Yellow amorphous substance; ¹H and ¹³C NMR data in CDCl₃, see **Table 1**; HRESIMS: *m/z* = 525.2063 [M+Na]⁺ (calcd. for C₃₄H₃₀NaO₄, 525.2036).

3-*O*-[α -L-rhamnopyranosyl-(1 \rightarrow 3)- β -D-glucopyranosyl] oleanolic acid (putranoside A, **3**) [37-40]: White amorphous substance; ¹H and ¹³C NMR data see **Table 1S** Supplementary content; HRESIMS: *m/z* = 801.4396 [M+Na]⁺ (calcd. for C₄₂H₆₆NaO₁₃, 801.4396).

3.6 Conformational analysis and geometrical optimization

Conformational analysis of compound **2** was accomplished with Schrödinger MacroModel 9.1 software employing the OPLS 2005 (optimized potential for liquid simulations) force field in H₂O. Conformers within a 1 Kcal/mol energy window from the global minimum were picked for geometrical optimization and energy calculation applying DFT with the B3LYP functional using the 6-31G (d,p) basis set in the gas phase with the Gaussian 09 program package (Frisch, 2009). Vibrational evaluation was done at the same level to confirm minima.

3.7 Bioassays

Extracts were tested *in vitro* against *Plasmodium falciparum* (NF54 strain), *Trypanosoma brucei rhodesiense* (STIB 900 strain), and *Leishmania donovani* (strain MHOM/ET/67/L82), in 96-well microtiter plates at concentrations of 10.0 µg/ml and 2.0 µg/ml. IC₅₀s were subsequently determined for active extracts. HPLC microfractions from the CH₂Cl₂/MeOH (1:1) stem extract of *D. gerrardii* were assayed against *P. falciparum* and *L. donovani*. Those from the CH₂Cl₂/MeOH (1:1) leaf extract were tested on *T. b. rhodesiense*. Compounds **1** and **3** were evaluated for their antiprotozoal activity against the three parasites. Due to the scarcity of isolated material, compound **2** was tested only against *P. falciparum*. Additionally, for pure compounds, cytotoxicity was determined by using a rat skeletal myoblast cell line (L-6 cells). For the assays DMSO stock solutions (10 mg/ml) of extracts and purified compounds were freshly diluted in medium (final DMSO concentration in assay <1%). Assays were performed in two independent replicates. *In vivo* antimalarial activity was assessed as previously described (Peters, 1987) and conducted according to the rules and regulations for the protection of animal rights ('Tierschutzverordnung') of the Swiss 'Bundesamt für Veterinärwesen'. They were approved by the veterinary office of the Canton Basel-Stadt, Switzerland. The animal experiment approval number for *in vivo* testing against *P. berghei* is 1731. Details on assay protocols are provided as Supplementary content.

Appendix A. Supplementary data

Supplementary data associated with this article can be found, in the online version, at

Acknowledgments

The authors thank the Council for Scientific and Industrial Research (CSIR), and the Swiss Confederation for financial support under the Swiss South African Joint Research Programme (grant JRP 03). Y. Hata gratefully acknowledges a PhD stipend from Administrative Department of Science and Technology from Colombia (Colciencias) managed by LASPAU. We thank Dr. D. Haussinger (Department of Chemistry, University of Basel) for recording the ^{13}C NMR spectrum of **2**, O. Fertig for GC-MS analysis, and Dr. M. Raith for her support in the structure elucidation. Thanks are also due to Mrs. M. Rogalski for proof-reading the manuscript.

Conflicts of Interest

The authors declare no conflict of interest.

Fig. 4 Key HMBC and NOESY correlations of compound **1**.

Fig. 5 Key HMBC and NOESY correlations for substructures **A** and **B** of compound **2**.

Fig. 6 DFT optimized conformers of compound **2**. Atoms CH₃-7 and H-4' showing a key NOESY correlation between the 2 substructures. Intramolecular distance between CH₃-7 and H-4' was 3.45 Å in both conformers.

Highlights

- HPLC-based activity profiling led us to identify the antiprotozoal compounds.
- A new phenanthrenone (**1**) with high antiplasmodial *in vitro* activity was discovered.
- A new heterodimer (**2**) with antiplasmodial *in vitro* activity was isolated.
- A saponin (**3**) was isolated and showed weak trypanocidal activity.

Appendix A

Supplementary data

Identification of two new phenathrenones and a saponin as antiprotozoal constituents of *Drypetes gerrardii*

Assays for *in vitro* Antiprotozoal Activity

Antiplasmodial activity was determined by a modification of the $^3\text{[H]}$ -hypoxanthine incorporation assay [1] with the *P. falciparum* NF54 strain, growth according to the method described by Trager and Jensen [2]. Chloroquine (purity >95%, Sigma-Aldrich) was used as positive control.

Briefly, a suspension of infected red blood cells (final parasitemia 0.3% and hematocrit 1.25%) in RPMI 1640 medium supplemented with 2 μM L-glutamine, 5.95 g/l Hepes, 2 g/l NaHCO_3 , and 5% of Albumax II was exposed to serial drug dilutions covering a range from 10 $\mu\text{g/mL}$ to 0.156 $\mu\text{g/mL}$ in 96-well microtiter plates. After 48 h of incubation (4% CO_2 , 3% O_2 , and 93% N_2 at 37°C), 50 μl of $^3\text{[H]}$ -hypoxanthine (0.25 μM) were added to each well (Costar). The plates were incubated for further 24 h before being harvested by using a Betaplate cell harvester (Wallac) onto glass-fiber filters and then washed with distilled water. The dried filters were inserted into plastic foils with 10 ml scintillation fluid. The radioactivity was counted with a Betaplate liquid scintillation counter (Wallac) as counts per minute per well at each drug concentration and compared to the untreated controls. Counts were expressed as percentages of the control and presented as sigmoidal inhibition curves. IC_{50} values were calculated by linear interpolation.

Antitrypanosomal activity against *T. brucei rhodesiense* STIB 900 was determined according to [3]. Melarsoprol (Arsorbal, purity >95%, Sanofi-Aventis) was used as positive control. Minimum essential medium (MEM) with Earle's salts supplemented with 2-mercaptoethanol, as described by Baltz *et al.* [4], 1 mM sodium pyruvate, 0.5 mM hypoxanthine, and 15% heat-inactivated horse serum was added (50 μl) to each well of a 96-well microtiter plate (Costar) except of the negative control. Serial drugs dilutions were prepared covering range from 90 to 0.123 $\mu\text{g/mL}$ followed by the parasite suspension of 2000 *T. brucei rhodesiense* STIB 900 bloodstream forms/well. After 70 hours of incubation (humidified 5% CO_2 atmosphere at 37°C), 10 μl resazurin solution (12.5 mg resazurin (Sigma-Aldrich) dissolved in 100 ml of distilled water) were added and incubation was continued for further 2 to 6 h. The plate was read with a Spectramax Gemini XS microplate fluorescence reader (Molecular Devices) with an excitation wavelength of 536 nm and an emission wavelength of 588 nm. Fluorescence development was expressed as percentage of the control and the IC_{50} values were determined from the sigmoid curves using Softmax Pro Software (Molecular Devices).

Leishmanicidal activity was determined with *L. donovani* (axenic amastigotes) MHOM-ET/67/L82 strain according to [5], with some modifications. Fifty microlitres of SM medium at pH 5.4 supplemented with 10% heat-inactivated FBS was added to each well of 96-well microtiter plate (Costar). Serial drug dilutions were prepared covering a range from 90 to 0.123 µg/ml. Then, 10^5 axenically growth *L. donovani* amastigotes in 50 µl medium, were added to each well and the plate was incubated for 72 h (humidified 5% CO₂ atmosphere at 37°C). Ten microlitres resazurin solution (12.5 mg resazurin (Sigma-Aldrich) dissolved in 100 ml of distilled water) were added to each well and incubated for further 2 to 4 h. The plate was read with a Spectramax Gemini XS microplate fluorescence reader (Molecular Devices) with an excitation wavelength of 536 nm and an emission wavelength of 588 nm. Fluorescence development was expressed as percentage of the control and the IC₅₀ values were determined from the sigmoid curves using Softmax Pro Software (Molecular Devices). Miltefosine (purity >95%, VWR) was used as positive control.

***In vitro* Cytotoxicity Assay**

The cytotoxicity assay was performed using a protocol based on the Alamar Blue assay [6], whereby rat skeletal myoblast cells (L-6 cells) were seeded in 96-well microtiter plates using MEM supplemented with 10% heat inactivated FBS (4000 cells/well). Serial threefold drug dilutions ranging from 90 to 0.123 mg/ml were prepared. After 72 h, 10 µl resazurin solution was added (12.5 mg resazurin (Sigma-Aldrich) dissolved in 100 ml of distilled water) and the plates were incubated for further 2 to 4 h. A Spectramax Gemini XS micro plate fluorescence reader (Molecular Devices) was used to measure the plates at an excitation wavelength of 536 nm and an emission wavelength of 588 nm. Fluorescence development was expressed as percentage of the control and the IC₅₀ values were determined from the sigmoid curves using Softmax Pro Software (Molecular Devices). Podophyllotoxin (purity >95%, Sigma-Aldrich) was used as a reference drug.

Assays for *in vivo* Antimalarial Activity

In vivo antimalarial activity was assessed basically as previously described [7]. Groups of three female NMRI mice (20–22 g) were intravenously infected with 2×10^7 with GFP-transfected *P. berghei* strain ANKA [8] parasitized erythrocytes on day 0. Compounds were dissolved in 100% DMSO, diluted 10-fold in distilled water and administered intraperitoneally in a volume of 10 ml/kg (dose of 50 mg/Kg) on four consecutive days (4, 24,

48 and 72 h post infection). Parasitemia was determined on day 4 post infection (24 h after last treatment) by FACS analysis. Activity was calculated as the difference between the mean per cent parasitemia for the control (n=5 mice) and treated groups expressed as a per cent relative to the control group. The survival time in days was also recorded up to 30 days after infection. A compound was considered curative if the animal survived to day 30 after infection with no detectable parasites. Mice were euthanized by carbon dioxide inhalation.

Protocol for Acid Hydrolysis of Compound 3

Compound **3** (2.0 mg) was dissolved in 4 ml of a mixture 1:1 of dioxane/TFA 2N and heated at 105°C for 2 h. The solvent was evaporated and the remaining solution was extracted three times with 1 ml of CHCl₃. TLC analysis of the organic phase revealed decomposition of the aglycone. The aqueous phase was dried and the residue re-dissolved in anhydrous pyridine. The sugars were derivatized with L-cysteine methyl ester hydrochloride (200 µl, 60°C, 1 h) and subsequently silylated with hexamethyldisilzane and chlorotrimethylsilane (Fluka) in pyridine (2:1:10, 300 µl; 60°C, 30 min). GC analysis on a capillary DB-225MS column (30 m x 0,25 mm i.d., 0,25 m; Agilent; column temp. 150°C for 2 min, then 5°C/min. to 210°C, then 10°C/min to 240°C).

3.6 Antiplasmodial and Antitrypanosomal Activity of Pyrethrins and Pyrethroids

Yoshie Hata, Stefanie Zimmermann, Melanie Quitschau, Marcel Kaiser, Matthias Hamburger, and Michael Adams

J. Agric. Food Chem., 2011, 59: 9172–9176. DOI: 10.1021/jf201776z

Five pyrethrins were isolated from *Chrysanthemum cinerariifolium*. Their antiprotozoal activity was evaluated against *Plasmodium falciparum* and *Trypanosoma brucei rhodesiense* and compared with synthetic pyrethroids. Pyrethrin II and Jasmolin II inhibited *P. falciparum*. Natural pyrethrins were more active than pyrethroids.

My contributions to this work were: (1) extraction of plant material; (2) isolation of pyrethrins; (3) recording and interpretation of analytical data for structure elucidation (HPLC-PDA-ESI-MS and 1D and 2D NMR), data analysis; (4) writing of the manuscript draft, preparation of figure, table, and supporting information.

In vitro antiplasmodial and cytotoxicity tests were performed by Stefanie Zimmermann in the Swiss TPH. Melanie Quitschau supervised structure elucidation.

S Supporting Information

ABSTRACT: In a screen of 1800 plant and fungal extracts for antiplasmodial, antitrypanosomal, and leishmanicidal activity, the *n*-hexane extract of *Chrysanthemum cinerariifolium* (Trevir.) Vis. flowers showed strong activity against *Plasmodium falciparum*. We isolated the five pyrethrins [i.e., pyrethrin II (1), jasmolin II (2), cinerin II (3), pyrethrin I (4), and jasmolin I (5)] from this extract. These were tested together with 15 synthetic pyrethroids for their activity against *P. falciparum* and *Trypanosoma brucei rhodesiense* and for cytotoxicity in rat myoblast L6 cells. The natural pyrethrins showed antiplasmodial activity with IC₅₀s between 4 and 12 μ M, and antitrypanosomal activity with IC₅₀s from 7 to 31 μ M. The pyrethroids exhibited weaker antiplasmodial and antitrypanosomal activity than the pyrethrins. Both pyrethrins and pyrethroids showed moderate cytotoxicity against L6 cells. Pyrethrin II (1) was the most selective antiplasmodial compound, with a selectivity index of 24.

KEYWORDS: *Chrysanthemum cinerariifolium*, Asteraceae, pyrethrins, pyrethroids, antiplasmodial, antitrypanosomal, malaria, trypanosomiasis

INTRODUCTION

Pyrethrum (*Chrysanthemum cinerariifolium* (Trevir.) Vis. (synonyms *Tanacetum cinerariifolium* (Trevir.) Schultz Bip. and *Pyrethrum cinerariifolium* (Trevir.)), a herbaceous perennial of the Asteraceae family, is the most widely used botanical insecticide. Currently, it is cultivated in Kenya, Australia, and United States of America, among other countries.^{1–3} The secondary metabolites responsible for the insecticidal activity of pyrethrum are six closely related esters of the pyrethric and chrysanthemic acids and the pyrethrolone, cinerolone, or jasomolone alcohols.^{1,3,4} Pyrethrins are very potent and selective natural insecticides. However, these compounds are quickly degraded when they are exposed to air and sunlight, which limits their efficacy.^{1,5}

To overcome instability issues, pyrethrin-inspired synthetic insecticides, the pyrethroids, were developed. They have increased photostability while maintaining the potent, rapid insecticidal activity, and relatively low acute mammalian toxicity of the pyrethrins.^{1,5} Currently, pyrethroids are used in agriculture and as active ingredients of household insecticidal products. They have been applied to control vectors of human diseases such as *Anopheles gambiae*, an important carrier for malaria transmission. As a result, pyrethrins occupy an important place in the world's insecticide market, representing 18% of the U.S. dollar value.^{5,6}

Pyrethroids can be classified into the classes type I and type II, the main structural difference being the presence of an α -cyano-3-phenoxybenzylalcohol moiety in type II pyrethroids.^{7–9} Pyrethrins and pyrethroids exert their insecticidal activity by modification of the insect's voltage-gated sodium channels by slowing the kinetics of channel gate activation and inactivation. This results

in increased anion permeability leading to membrane depolarization and a subsequent rise of neuronal action potential.^{5,10,11} Besides sodium channels, pyrethrins and pyrethroids can interact with voltage-gated calcium, potassium, and chloride channels, as well as GABA, glutamate, and acetylcholine receptors.^{5,8,10}

Pyrethrins and type I pyrethroids have quantitatively and qualitatively different effects than the type II pyrethroids on ion channels and different visible effects on insects.^{7–11}

The biological activity of pyrethrins beyond their insecticidal properties has not been extensively investigated. However, some data on antimycobacterial (*M. avium* and *M. tuberculosis* H37Rv) and antiviral properties (Herpes Simplex Virus, HSV-1, MacIntyre strain ATCC No. VR-539 and HSV-2, MS strain)^{4,12} have been reported.

Our interest in pyrethrum was raised when, in a project for natural product based lead discovery, we performed an antiprotozoal screen of 1800 plant and fungal extracts for effects against the parasites *Trypanosoma brucei rhodesiense*, *Trypanosoma cruzi*, *Plasmodium falciparum*, and *Leishmania donovani*. These protozoal parasites are the causal agents of human African trypanosomiasis, Chagas disease, malaria, and leishmaniasis, respectively. The extract library included an *n*-hexane extract of pyrethrum flowers that exhibited potent activity against *P. falciparum* and *T. brucei rhodesiense* at a test concentration of 4.8 μ g/mL; the inhibition was 87% and 99%, respectively. To identify the compounds responsible for the activity, a series of pyrethrins

Figure 1. Structures of the pyrethrins 1–5, type I pyrethroids 6–11, and type II pyrethroids 12–20. The commercial pyrethroids (6–20) are diastereomeric mixtures, with the exception of 11 (*Z*)-(1*S*,3*S*) and 12 (*S*)-(1*R*,3*R*).

(Figure 1) were isolated from the *n*-hexane extract and evaluated for their *in vitro* antiprotozoal activity. Since the natural products showed activity against the two protozoan parasites, we included six type I pyrethroids and nine type II pyrethroids (Figure 1) to evaluate their effects on the parasites too. The idea was that these commercial compounds, if exerting their antiprotozoal activity possibly on the same targets as the active natural products, might be good leads due to their favorable physicochemical properties, potency, and stability. Besides the antiprotozoal activity, cytotoxicity in rat L6-cells was determined to assess the selectivity of an inhibitory effect on the parasites rather than mammalian cells.

MATERIALS AND METHODS

General Experimental Procedures. Analytical grade solvents for extraction and HPLC grade solvents for chromatography were

purchased from Scharlau (Barcelona, Spain). HPLC grade water was obtained by an EASY-pure II from a Barnstead water purification system (Dubuque, Iowa). Formic acid (98.0–100.0%) was from Sigma-Aldrich (Buchs, Switzerland). Artemisinin was obtained from Sigma Aldrich (Buchs, Switzerland) and melarsoprol (Arsobal) from Sanofi-Aventis, (Geneva, Switzerland). The pyrethroids tetramethrin (10), bifenthrin (11), τ -fluvalinat (19), and flucythrinate (20) were purchased from Sigma-Aldrich (Buchs, Switzerland). Dr. Ehrenstorfer GmbH (Augsburg, Germany) provided phenothrin (6), allethrin (7), resmethrin (8), permethrin (9), deltamethrin (12), cyphenothrin (13), λ -cyhalothrin (14), cypermethrin (15), cyfluthrin (16), fenpropathrin (17), and fenvalerate (18).

Preparative HPLC was done on a LC-8A preparative system consisting of two Model LC-8A pumps, a Model SPD-M10A VP PDA detector, and VP2 software (all from Shimadzu, Tokyo, Japan). Medium pressure liquid chromatography (MPLC) was performed using a Büchi

Sepacore system (Büchi, Flawil, Switzerland), consisting of a control unit C-620, a fraction collector C-660, a UV photometer C-635, and two pump modules C-605, on a prepacked silica gel (40–63 μm) polypropylene cartridge (40 \times 150 mm, Büchi). TLC was conducted on precoated Kieselgel 60 F₂₅₄, 0.25 mm plates (Merck, Darmstadt, Germany). NMR data were acquired at a target temperature of 18 °C on an Avance III 500 MHz spectrometer (Bruker, Fällanden, Switzerland) operating at 500.13 MHz for ¹H and 125.77 MHz for ¹³C. A 1 mm TXI-microprobe with a z-gradient was used for ¹H-detected experiments. For processing and evaluation Topspin 2.1 (Bruker) software was used. NMR experiments were done as previously described.¹³

Plant Material. Dried flowers of *Chrysanthemum cinerariifolium* (Trevir.) Vis. (Asteraceae) were purchased from Dixa AG (St. Gallen, Switzerland). A voucher specimen (NL 769) is deposited at Herbarium of the Division of Pharmaceutical Biology, University of Basel, Switzerland.

Extraction and Isolation. One kilogram of finely ground plant material was extracted three times with three liters of *n*-hexane for two hours each, at room temperature. Extracts were combined, and the solvent was evaporated at reduced pressure to yield 16.2 g of crude extract. The pyrethrins were isolated from this extract by preparative chromatography in two steps. The first isolation step consisted of MPLC. A portion (10.9 g) of extract was separated on a silica gel prepacked cartridge (40 \times 150 mm) by gradient elution with 0–25% ethyl acetate in *n*-hexane over 4 h. The flow rate was 20 mL/min. Fractions were collected every 60 s and compared by TLC [mobile phase: ethyl acetate/*n*-hexane (25:75 v/v)]. Pyrethrins were detected as dark blue spots after spraying with vanillin sulfuric acid reagent (solvent A, vanillin 1% in ethanol; and solvent B, ethanolic solution of sulfuric acid 10%) and heating at 110 °C.¹⁴ Similar fractions were pooled to give two pyrethrin-enriched fractions 3 (570 mg) and 6 (118 mg). Preparative HPLC was used for the isolation of pyrethrins from these fractions. The column employed was a SunFire RP-18 column (5 μm , 30 mm \times 150 mm; Waters, Wexford, Ireland). The mobile system was water (solvent A) and methanol (solvent B) using the following gradient: 50% B to 100% B in 30 min, then 100% B for 5 min. The flow rate was 20 mL/min. Sixty milligrams of the fraction in 300 μL of tetrahydrofuran was injected in each run. The UV absorption was monitored at 230 nm.

From fraction number 3, we isolated pyrethrin I (4) (10.4 mg), jasmolin I (5) (0.8 mg), and jasmolin II (2) (0.7 mg). Fraction 6 afforded pyrethrin II (1) (9.4 mg) and cinerin II (3) (0.6 mg). Extract, fractions, isolated pyrethrins, as well as all the commercial pyrethroids were stored protected from light and oxygen, at 2–8 °C under an argon atmosphere.

The structures of pyrethrins were established by 1D and 2D NMR (COSY, HMBC, HSQC, and NOESY). The data are provided as Supporting Information and are in good accordance with the literature.^{3,4,15} Purity of pyrethrins was >95% as determined by the integration of ¹H NMR spectra.

Biological Tests. The *n*-hexane extract, pyrethrins, and the synthetic pyrethroids were dissolved in DMSO to obtain a final stock solution concentration of 10 mg/mL. The samples were stored at –20 °C until they were used. Further dilutions were done in media so that the DMSO concentration in the highest test concentration before serial dilution was <1%. The screening of the extract library against *P. falciparum* and *T. brucei rhodesiense* was performed in 96 well plates (Costar, Kennebunk, ME), at concentrations of 4.81 and 0.81 $\mu\text{g/mL}$.¹⁶ Tests were done in triplicate and repeated twice. IC₅₀ values against both parasites as well as rat myoblasts (L6-cells) were determined by serial dilution in duplicate and repeated three times.

Testing against *P. falciparum* K1 Strain. A modification of the [³H]-hypoxanthine incorporation assay was used to determine intraerythrocytic inhibition of parasite growth. Infected erythrocytes (final parasitemia and hematocrit were 0.3% and 1.25%, respectively) in RPMI 1640 medium were exposed to 2-fold serial drug dilution in 96 well plates (Costar, Kennebunk, ME), which covered a range from 10 $\mu\text{g/mL}$

(19.8 to 33.1 μM) to 0.156 $\mu\text{g/mL}$ (0.31 to 0.52 μM). After 48 h of incubation, 50 μL of [³H]-hypoxanthine (0.5 μCi) in the medium was added, and plates were incubated for an additional 24 h. Parasites were harvested onto glass-fiber filters, and radioactivity was counted using a Betaplate liquid scintillation counter (Wallac, Zürich, Switzerland). The results were recorded as counts per minute (cpm) per well at each drug concentration and expressed as a percentage of untreated controls.^{13,16}

Testing against *T. brucei rhodesiense* STIB 900. Minimum essential medium (MEM) supplemented with 2-mercaptoethanol and 15% heat-inactivated horse serum was used for determining the inhibition of parasite growth. Serial 3-fold drug dilution, which covered a range of 90 $\mu\text{g/mL}$ (178 to 298 μM) to 0.123 $\mu\text{g/mL}$ (0.24 to 0.41 μM), was prepared in 96 well plates. Bloodstream forms of *T. brucei rhodesiense* in 50 μL of medium were added to each well except of the background. The plate was incubated under humidified 5% CO₂ atmosphere at 37 °C for 68 h. Resazurin (Sigma-Aldrich, Zürich, Switzerland) solution (12.5 mg of resazurin dissolved in 100 mL of distilled water; 10 μL) was then added to all wells and the incubation continued for a further 2 to 4 h. The plate was read in a Spectramax Gemini XS micro plate fluorometer (Molecular Devices Cooperation, Sunnyvale, CA) using an excitation wavelength of 536 nm and an emission wavelength of 588 nm. Fluorescence development was measured and expressed as a percentage of the control.^{16,17}

Cytotoxicity Test Using L6 Cells. The rat skeletal myoblast cell line (L-6 cells) was used to assess cytotoxicity. The cells were seeded in RPMI 1640 medium supplemented with 1% L-glutamine (200 nM) and 10% fetal bovine serum under humidified 5% CO₂ at 37 °C. Assays were performed in 96 well microtiter plates, with each well receiving 100 mL of culture medium with 4 \times 10⁴ cells. After 24 h, the medium was removed from all wells, and serial 3-fold drug dilutions were prepared covering a range from 90 (178.1 to 297.9 μM) to 0.123 $\mu\text{g/mL}$ (0.24 to 0.41 μM). After 68 h of incubation, the plates were inspected under an inverted microscope to ensure the growth of the controls and sterile conditions. Then, 10 μL of resazurin solution (12.5 mg of resazurin dissolved in 100 mL of distilled water) was added to each well, and the plates were incubated for another 2 h. Then, the plates were read with a Spectramax Gemini XS Microplate fluorometer (Molecular Devices Cooperation, Sunnyvale, CA) using an excitation wavelength of 536 nm and an emission wavelength of 588 nm. IC₅₀ values were determined using the microplate reader software Softmax Pro (Molecular Devices Cooperation, Sunnyvale, CA).¹⁸

RESULTS AND DISCUSSION

A medium throughput screen showed that the *n*-hexane extract of *C. cinerariifolium* flowers had significant activity against *P. falciparum* (86% inhibition at a test concentration of 4.8 $\mu\text{g/mL}$) and against *T. brucei rhodesiense* (99% inhibition at the same concentration). Since highly lipophilic pyrethrins are the characteristic secondary metabolites in an *n*-hexane extract of pyrethrum flowers, we carried out a targeted isolation of pyrethrins. Among the compounds extracted were three esters of pyrethric acid, [pyrethrin II (1), jasmolin II (2), and cinerin II (3)], and two esters of chrysanthemic acid, [pyrethrin I (4) and jasmolin I (5)] (Figure 1). When tested against *P. falciparum*, *T. brucei rhodesiense*, and L-6 cells, most of these exhibited antiprotozoal activity and low cytotoxicity (Table 1). The most active compound in the antiplasmodial assay was 1 with an IC₅₀ of 4.0 \pm 1.1 μM , followed by 2 and 3 with IC₅₀ values of 5.0 \pm 0.4 and 5.8 \pm 0.4 μM , respectively. Compounds 4 and 5 were somewhat less active (IC₅₀ values of 11.7 \pm 1.5 and 9.3 \pm 1.2 μM , respectively). Accordingly, the three derivatives of pyrethric acid showed the most potent antiplasmodial effect.

Table 1. In Vitro Antiprotozoal Activities of Isolated Natural Pyrethrins 1–5 and Synthetic Pyrethroids 6–20 against *Plasmodium falciparum* and *Trypanosoma brucei rhodesiense*, Cytotoxic Activity in L-6 Cells, and Selectivity Indices (IC₅₀ L-6 cells/IC₅₀ parasite)^a

compound	IC ₅₀ (μM) ± SEM			selectivity index

^a n.d. not determined. SEM: standard error of the mean. Selectivity index: quotient of the activity of the compounds on the parasites and the mammalian cells. ^b No activity observed at the highest test concentration of 10 μg/mL, which corresponds to molar test concentrations of 19.8 to 33.1 μM. ^c No activity observed at the highest test concentration of 90 μg/mL, which corresponds to molar test concentrations of 178 to 298 μM. ^d Reference drug *P. falciparum* assay. ^e Reference drug *T. b. rhodesiense* assay. ^f Reference drug cytotoxicity assay.

The antitrypanosomal activity of the isolated compounds was less pronounced (Table 1). Pyrethrin I (4) showed an IC₅₀ of 6.9 ± 1.1 μM. The IC₅₀ values of compounds 1, 2, 3, and 5 were above 10 μM (10.6 ± 0.4, 12.1 ± 0.2, 12.2 ± 0.02, and 30.9 ± 1.4 μM, respectively).

The compound with the lowest cytotoxicity against L6 cells was 4 followed by 1 (Table 1). With a SI of 23.6, pyrethrin II (1) was the most selective compound against *P. falciparum*. The other four pyrethrins showed selectivity indices (SI) between 4.9 and 12.6 (Table 1). Pyrethrin I (4) showed the highest SI (21.2) against *T. brucei rhodesiense*, while the other four pyrethrins exhibited SI between 2.3 and 9.0.

We then tested a series of 6 type I (6–11) and 9 type II pyrethroids (12–20). Type I pyrethroids were more active against *P. falciparum* than type II compounds but less active than the pyrethrins (1–5), with the exception of 11, which showed an IC₅₀ of 8.9 ± 2.0 μM. Six (12–16 and 19) of the nine type II pyrethroids did not show antiparasitic activity at the highest tested concentration of 10 μg/mL. This corresponds to the molar test concentrations ranging from 19.8 to 33.1 μM for the various substances (Table 1).

Both, type I and type II pyrethroids displayed low activity against *T. brucei rhodesiense* (Table 1). Their IC₅₀ values were in the range of 12.9 ± 2.2 μM for 10 (a type I pyrethroid) and

57.8 ± 6.2 μM for 18 (a type II pyrethroid). Selectivity toward the protozoa was low.

In conclusion, pyrethrins were the compounds responsible for the antiparasitic activity of the lipophilic pyrethrum extract. These compounds had reasonably selective antiparasitic properties and weaker trypanocidal activity. Among them, pyrethrin II (1) was the most active and selective compound. In contrast, all 15 pyrethroids showed a weaker and less selective inhibition on *P. falciparum* and *T. brucei rhodesiense*.

As mentioned above, the main target for pyrethrins and pyrethroids in insects are voltage-gated sodium channels. Neither in *P. falciparum* nor in *T. brucei rhodesiense* has the presence of such channels been reported.^{19–21} The antiprotozoal effects reported here may involve some of the other channels or structurally related ones with which pyrethrins and pyrethroids can interact. For instance *T. brucei rhodesiense* has potassium channels,¹⁹ and *P. falciparum* has channels such as aquaporin PfAQP, which could possibly be targets for these compounds.^{20,21}

3.7 Antitrypanosomal Sesquiterpene Lactones from *Saussurea costus*

Tasqiah Julianti, **Yoshie Hata**, Stefanie Zimmermann, Marcel Kaiser, Matthias Hamburger, Michael Adams

Fitoterapia, 2011, 82: 955–959. DOI: 10.1016/j.fitote.2011.05.010

As a contribution to the structure activity relationship (SAR) of trypanocidal sesquiterpene lactones from different botanical sources, the activity of the germacrolides costunolide, eupatoriopicrin, and partenolide was compared with the activity of guaianolides dehydrocostuslactone and zaluzanin D, and the eudesmanolides arbusculin B and α -cyclocostunolide. The germacrolides were the most active class of sesquiterpene lactones.

My contributions to this work were: (1) recollection of Eupatorium cannabinum; (2) extraction of plant material; (3) isolation of the sesquiterpene lactone eupatoriopicrin; (4) recording and interpretation of analytical data for structure elucidation (HPLC-PDA-ESI, TOF-MS, 1D and 2D NMR); (5) extraction of plant material of Laurus nobilis; (6) isolation of the sesquiterpene lactones costunolide and zaluzanin D; (7) recording and interpretation of analytical data for structure elucidation (HPLC-PDA-ESI, TOF-MS, 1D NMR and 2D NMR); (8) providing the corresponding data for manuscript, figure, table, and supporting information preparation.

Inken Plitzko and Melanie Quitschau supervised structure elucidation. In vitro trypanocidal and cytotoxicity tests were performed by Stefanie Zimmermann in the Swiss TPH. Tasqiah Julianti isolated costunolide, dehydrocostuslactone, and other sesquiterpenelactones from S. costus and wrote the manuscript draft.

Sesquiterpene lactones

Trypanosoma brucei rhodesiense

HPLC-based activity profiling

ABSTRACT

In the course of a larger screen of 1800 plant and fungal extracts, the ethyl acetate extract of *Saussurea costus* roots potently inhibited the growth of *Trypanosoma brucei rhodesiense*. Subsequent HPLC based activity profiling led to the identification of the sesquiterpene lactones arbusculin B (1), α -cyclocostunolide (2), costunolide (3), and dehydrocostuslactone (4). They were tested for in vitro antitrypanosomal activities and cytotoxicity alongside the structurally related sesquiterpene lactones parthenolide (5), zaluzanin D (6), and eupatoriopicrin (7), and had IC₅₀s between 0.8 and 22 μ M. Cytotoxic IC₅₀s were from 1.6 to 19 μ M, and selectivity indices from 0.5 to 6.5.

1. Introduction

The fragrant roots of *Saussurea costus* (Falc.) Lipschitz (Asteraceae), synonym: *Saussurea lappa* C.B. Clarke, have been used for thousands of years as medicines, incenses and ointments by many cultures. In India they are called Kur or Kushtha, and in China *Yún mù xiāng* (云木香). In the Ayurveda, Siddha, and Unani medicinal systems *S. costus* roots are used alone or in combination with other drugs to treat asthma, cholera, chronic skin diseases, rheumatism, cough and cold, quartan malaria, leprosy, persistent hiccups, rheumatism, stomach-ache, toothache, and typhoid fever [1,2].

A broad spectrum of biological activities such as anti-inflammatory, anticancer, immunomodulatory, CNS depressant, and antimicrobial properties have been reported for *S. costus* extracts [3–5]. Activities have commonly been related

to the presence of sesquiterpene lactones. Furthermore, tannins, steroids, alkaloids, glycosides, terpenoids, flavonoids, peptides, and organic acids have been reported from this plant [3,4].

Our interest in this plant was raised when we performed an antiprotozoal screen of 1800 plant and fungal extracts for effects against the parasites *Trypanosoma brucei rhodesiense*, *Trypanosoma cruzi*, *Plasmodium falciparum* and *Leishmania donovani*, the causal agents of human African trypanosomiasis, Chagas disease, malaria, and leishmaniasis, respectively [6–8]. Amongst the most potent extracts in this screen was an ethyl acetate extract of *S. costus* roots which inhibited *T. b. rhodesiense* by 96% at a test concentration of 4.8 μ g/ml.

HPLC based activity profiling was used to identify the active constituents in the extract. In this approach sub-milligramme amounts of extract are separated by analytical scale HPLC and automatically fractionated into 96 well plates. The microfractions obtained are submitted to the bioassay, and the resulting activity profile can be overlaid with the HPLC trace to correlate peaks of activity with peaks in the HPLC chromatogram. On-line spectroscopic data (UV–Vis and MS) collected during separation, combined with database

searches provide structural information on the active principles [6–8].

We here report on the identification and isolation of antitrypanosomal compounds from *S. costus*, and also on the comparative testing of some related sesquiterpene lactones for antiprotozoal and cytotoxic activities. This study was part of a larger screen for new antiprotozoal leads using HPLC based activity profiling which has led to the identification of numerous active compounds [8–11].

2. Materials and methods

2.1. General experimental procedures

Analytical grade solvents for extraction and HPLC-grade eluents for chromatography were purchased from Scharlau (Barcelona, Spain), if not stated otherwise. HPLC-grade water was obtained with an EASY-pure II water purification system (Barnstead; Dubuque, IA, USA). Formic acid was from Sigma-Aldrich (Buchs, Switzerland).

Initial screening of the extract library was done as previously described [6]. HPLC based activity profiling: Separations for microfractionation and for on line data collection were carried out on an Agilent series 1100 system equipped with degasser, binary high pressure mixing pump, column oven and PDA detector (all from Agilent; Waldbronn, Germany). MS spectra were recorded in the range of m/z 200–1500 positive and negative mode on an Esquire 3000 Plus ion trap mass spectrometer equipped with an electrospray interface (Bruker Daltonics; Bremen, Germany). Microfractionation was performed with 350 μ g of extract in DMSO (10 mg/ml) which were separated on a RP-HPLC SunFire C18 column (3.5 μ m, 3 \times 150 mm) (Waters; Wexford, Ireland) with gradient A (water + 0.1% formic acid) and B (acetonitrile + 0.1% formic acid), 10–100% B in 30 min and hold at 100% B for 2 min, at a flow rate of 0.5 ml/min. Hystar 3.2 software (Bruker Daltonics; Bremen, Germany) was used to monitor the HPLC system. An FC 204 fraction collector (Gilson; Middleton, WI, USA) was attached to the HPLC to collect a total of 32 microfractions of 60 s each into 96-deep well plates (Whatman; Florham Park, NJ, USA). The plates were dried in a Genevac EZ-2 PlusTM vacuum centrifuge (Avantec; Ipswich, UK), and microfractions redissolved in 5 μ l of DMSO prior to testing for antitrypanosomal activity as described [6].

Semipreparative HPLC for compound isolation was done on an Agilent 1100 series HPLC system consisting of a 1100 series quaternary low-pressure mixing pump with degasser module, column oven, and a 1100 series PDA detector with a 1000 μ l loop. A SunFire C18 column (5 μ m, 10 \times 150 mm) (Waters) was used. The mobile phase was: A (water) and B (MeOH) with a gradient of 60–100% B in 20 min, followed by flushing 5 min with 100% B, the flow rate was 5 ml/min, and monitored at 220 nm. In each run 15 mg of fraction in 50 μ l DMSO was injected.

High resolution HPLC–MS was recorded with an Agilent 1100 series HPLC linked to a microTOF-ESI-MS system (Bruker). MS calibration was performed using a reference solution of sodium formate 0.1% in isopropanol–water (1:1) containing 5 mM sodium hydroxide. The typical mass

accuracy was ± 3 ppm. HyStar 3.0 software (Bruker Daltonics) was used for data acquisition and processing.

NMR experiments were recorded in d_6 -DMSO and $CDCl_3$ on a Bruker Avance III spectrometer (Bruker; Fallanden, Switzerland) operating at 500.13 MHz at a target temperature of 18 °C. 1H NMR, COSY, HSQC, and HMBC spectra were measured with a 1 mm TXI probe. The 2D pulse programs were hsqcedetpg, hmbcgp1ndqf, and cosygpqf. Spectra processing and analysing was done with Bruker TopSpin 2.1 software.

2.2. Plant material

The dried roots of *S. costus* (MTS 577) were purchased from Peter Weinfurth in 2008 (Bochum, Germany). The leaves of *Laurus nobilis* L. (MTS 693) were purchased from Dixa AG (St. Gallen, Switzerland). The aerial parts of *Eupatorium cannabinum* L. (MTS 771) were harvested near Liestal, Canton Basel Land, Switzerland. The authentication of collected *E. cannabinum* was carried out by Dr. M. Adams. Voucher specimens of all samples are deposited at the Institute of Pharmaceutical Biology, University of Basel, organised under the MTS numbers shown above.

2.3. Extraction and preparative isolation

Dried roots of *S. costus* were finely ground using a ZM1 ultra centrifugal mill (Retsch; Haan, Germany). Maceration of 900 g of the powdered material four times with 4 l of ethyl acetate overnight at room temperature in a glass column 15 \times 26 cm (Pyrex, Ostermundigen, Switzerland) yielded 40 g of a thick brown extract. An aliquot of 30 g of extract was fractionated by open column chromatography (9 \times 59 cm) filled with silica gel (Kieselgel 60TM, particle size 40–63 μ m) (Merck; Darmstadt, Germany) and isocratic elution with *n*-hexane–ethyl acetate (9:1) at a flow rate of 20 ml/min. Fractions of 500 ml each were collected and monitored with TLC on pre-coated Kieselgel 60 F₂₅₄, 0.25 mm plates from Merck with a mobile phase of: toluene:ethyl acetate (9:1); detection with vaniline–H₂SO₄. Similar fractions were pooled resulting in 7 fractions. Fraction 5 was obtained as a brown oil (160 mg) and was separated by semi-preparative HPLC as described above to obtain compounds arbusculin B (**1**) (2.5 mg) and α -cyclocostunolide (**2**) (26 mg). Fraction 6 totalling 2.2 g afforded pure costunolide (**3**) (670 mg) and fraction 7 (9.7 g) gave dehydrocostuslactone (**4**) (6.5 g).

Zaluzanin D (**6**) from the ethyl acetate extract of the dried leaves of *Laurus nobilis* L. (Myrtaceae) and eupatoriopicrin (**7**) from the aerial parts of *Eupatorium cannabinum* L. (Asteraceae) were isolated by semipreparative HPLC as described above. Isolated substances **1–4**, **6**, and **7** were more than 95% pure according to their 1H NMR spectra. Parthenolide (**5**) was purchased from Alexis Biochemicals (Lausen, Switzerland) with more than 95% pure as stated by the supplier. The compounds **7** were identified by comparison of 1D and 2D 1H NMR, HPLC–HRTOF–MS data with published studies: **1** [12], **2** [13], **3** and **4** [14,15], **6** [16], and **7** [17]. Proton and carbon NMR data of all the isolated compounds are given in the supporting information (Table S1).

2.4. Antitrypanosomal assay

Preparation of *T. b. rhodesiense* STIB 900 stocks and culture media for the bloodstream forms was done according to Baltz et al. [18] with the following modifications: 2-mercaptoethanol 0.2 mM, sodium pyruvate 1 mM, hypoxanthine 0.5 mM, and 15% heat-inactivated horse serum. In vitro screening for antitrypanosomal activity was done with of Alamar Blue® assay [19]. Stock solutions of test compounds and their serial dilutions (5 µl) were transferred into 96 well plates (Costar; Corning Inc., Lowell, MA, USA) containing 50 µl of culture medium per well. Bloodstream forms of STIB 900 in 45 µl of medium were added to each well and the plate was incubated at 37 °C under 5% CO₂ atmosphere for 72 h. Ten microliters of resazurin solution (12.5 mg dissolved in 100 ml distilled water) (Sigma-Aldrich; Zürich, Switzerland) was then added and incubated for further 2–4 h. The fluorescence development was measured in a Spectramax Gemini XS microplate fluorometer (Molecular Devices Corp.; Sunnyvale, CA, USA), operating with an excitation wavelength of 536 nm and an emission wavelength of 588 nm and expressed as percentage of the control. The IC₅₀ values were calculated in the graphic programme Softmax Pro (Molecular Devices Corp.). Tests were done at least in three independent experiments in duplicate.

2.5. Cytotoxicity assay

Cytotoxicity was determined using rat skeletal myoblast (L6 cells). The culture medium was RPMI 1640 medium supplemented with L-glutamine 2 mM, HEPES 5.95 g/l, NaHCO₃ 2 g/l and 10% foetal bovine serum. Podophyllotoxin (Sigma-Aldrich) was used as the reference drug. The assay was performed following the antitrypanosomal assay protocol [19]. The IC₅₀s were calculated from the sigmoidal growth inhibition curves using Softmax Pro software (Molecular Devices Corp.). Tests were done in three independent experiments in duplicate.

3. Results and discussion

The preliminary screen of our in house extract library showed the ethyl acetate extract of *S. costus* to be highly active against *T. b. rhodesiense* with 96% inhibition at 4.8 µg/ml. This extract was subjected to HPLC based activity profiling to track the activity and identify the active principles. The activity was almost entirely focused in minutes 22 and 23 with 99% to 100% of inhibition. Fig. 1 shows the overlay of the chromatogram (ESI positive MS trace at scan *m/z* 200–1500) with the percent inhibition of these microfractions. Subsequently, compounds **3** and **4** from these two active windows were isolated.

The major compound **3** (*t_R* 22.4 min) had a molecular formula of C₁₅H₂₀O₂ with *m/z* 465.3182 [2M + H]⁺ (calcd. for C₃₀H₄₁O₄ 465.3006) and was identified as costunolide. Compound **4** (*t_R* 23.0 min) with a molecular formula of C₁₅H₁₈O₂ derived from *m/z* 461.2869 [2M + H]⁺ (calcd. for C₃₀H₃₇O₄ 461.2693) was dehydrocostuslactone. In addition, compounds **1** (*t_R* 24.2 min) and **2** (*t_R* 25.3 min) were isolated and both had the sum formula C₁₅H₂₀O₂ as suggested by the *m/z* 465.3185 [2M + H]⁺ (calcd. for C₃₀H₄₁O₄ 465.3006) and *m/z* 465.3190 [2M + H]⁺ (calcd. for C₃₀H₄₁O₄ 465.3006). They were identified as the known compounds arbusculin B (**1**) and α-cyclocostunolide (**2**) (Fig. 2).

Compounds **2**, **3**, and **4** have been isolated from *S. costus* previously [20]. Whilst compound **1** is reported here for the first time from this plant.

Further possibly active compounds present in the extract in minor concentrations, like the peaks seen in minute 11 and 20, were not isolated. This may be done in further studies.

From *L. nobilis* we isolated the sesquiterpene lactone **6** and from *Eupatorium cannabinum* substance **7**. Compound **6** with sum formula of C₁₇H₂₀O₄, *m/z* 311.1289 [M + Na]⁺ (calcd. for C₁₇H₂₀O₄Na 311.1254) was determined as zaluzanin D and compound **7** with molecular formula of C₂₀H₂₆O₆, *m/z* 385.1614 [M + Na]⁺ (calcd. for C₂₀H₂₆O₆Na 385.1622) was characterised as eupatoriopicrin. Substance **5** was from a commercial source. The ¹H and ¹³C NMR data

Fig. 1. The antitrypanosomal activity of the 32 one-minute microfractions plotted against the mass trace of the ethyl acetate extract of *Saussurea costus* (ESI-MS positive scan *m/z* 200–1500).

Fig. 2. Chemical structures of seven sesquiterpene lactones isolated from *Saussurea costus* (**1–4**), *Laurus nobilis* (**6**) and *Eupatorium cannabinum* (**7**). Compound **5** was from a commercial source.

for compounds **1–4**, **6**, and **7** are attached as supporting information (Table S1).

Sesquiterpene lactones are classified into several classes based on their carbocyclic skeleton [21]. The compounds in this study are eudesmanolides (6/6 bicyclic), germacranolides (10 member-ring monocyclic), and guaianolides (5/7 bicyclic).

The antitrypanosomal and cytotoxic IC_{50} of the 7 compounds were established (Table 1). The three germacranolides parthenolide (**5**), eupatoriopicrin (**7**), and costunolide (**3**) were the most antitrypanosomally active compounds in this study, followed by the guaianolides dehydrocostuslactone (**4**) and zaluzanin D (**6**), and the eudesmanolides arbusculin B (**1**), and α -cyclocostunolide (**2**). The cytotoxicity

of all compounds was within range of IC_{50} s from 1.6 to 19.4 μ M and selectivity indices between 0.5 and 6.5.

The three active germacranolides **3**, **5**, and **7** had similar IC_{50} values, suggesting that the presence of the epoxide in **3** or the esterified hydroxyl side chain in **7** did not greatly affect the antitrypanosomal activity. Compounds **3** and **5** were more selective towards *T. b. rhodesiense* than towards mammalian cells (SI: 5.9 and 6.5) whereas **7** was more toxic (SI: 1.3). Amongst the guaianolides, dehydrocostuslactone (**4**) had the threefold activity and twofold toxicity of zaluzanin D (**6**). They both had similar selectivity indices (1.9 and 1.4). The lowest antitrypanosomal activities and selectivities were seen for the two eudesmanolides arbusculin B (**1**) and α -cyclocostunolide (**2**) which were both more active against mammalian cells than against the parasites with selectivity indices of 0.5 and 0.9.

Lirussi et al. [22] report the potent inhibition (IC_{50} = 2.4 μ g/ml) of *T. cruzi* epimastigotes by a methanol extract of *S. costus* roots. Schmidt et al. [23] report parthenolide (**5**) to be highly active against *T. b. rhodesiense* and *T. cruzi*. The study also shows that the tested eudesmanolides tended to have lower antitrypanosomal activities and selectivities than some other types of sesquiterpene lactones. Izumi et al. [24] also previously publish the potent effect of parthenolide (**5**) against *T. cruzi*. The other compounds in this study have so far not been tested for antitrypanosomal effects. We recently reported the potent in vitro and in vivo activity of cynaropicrin, a guaianolide sesquiterpene lactone with a 2-hydroxymethyl-2-propenoyl moiety at C-8, against *T. b. rhodesiense* [9].

Sesquiterpene lactones may exert their various biological activities by the interaction of their α -methylene- γ -butyrolactone moiety with the thiol groups of biomacromolecules through Michael-addition [25].

Table 1

In vitro antitrypanosomal activity and cytotoxicity of sesquiterpene lactones against *T. b. rhodesiense* and cytotoxic effects against L6 cells. Results are expressed as IC_{50} values with the standard deviation (SD) and shown alongside the positive controls.

Compound	<i>T. b. rhodesiense</i>	L6 cells	SI
	IC_{50} (μ M \pm SD)	IC_{50} (μ M \pm SD)	
1 Arbusculin B	12.0 \pm 3.3	6.2 \pm 2.3	0.5
2 α -Cyclocostunolide	21.9 \pm 1.1	19.4 \pm 7.9	0.9
3 Costunolide	1.3 \pm 0.4	7.7 \pm 1.3	5.9
4 Dehydrocostuslactone	4.4 \pm 1.4	8.3 \pm 1.9	1.9
5 Parthenolide	0.8 \pm 0.5	5.2 \pm 0.9	6.5
6 Zaluzanin D	10.8 ^a	15.6 ^a	1.4
7 Eupatoriopicrin	1.2 \pm 0.2	1.6 \pm 0.08	1.3
Melarsoprol	0.006 \pm 0.003		
Podophyllotoxin		0.01 \pm 0.002	

^a IC_{50} value is obtained from a single experiment done in duplicate.

A comprehensive study on 40 sesquiterpene lactones from five sesquiterpene lactone classes confirms the influence of this α -methylene- γ -butyrolactone moiety to their antitrypanosomal and cytotoxic activity. The most potent and selective sesquiterpene lactones reported so far were the pseudoguaianolide helenalin and the xanthanolide 8-epixanthatin-1,5-epoxide. However, a high degree of correlation is also found between such compounds' antiprotozoal activity and mammalian cytotoxicity so that it may be difficult to find a structural explanation for the selectivity observed with some compounds [23]. Cytotoxicity studies of sesquiterpene lactones related to the lactone moiety were shown by Kupchan et al. [26,27].

This study suggests that sesquiterpene lactones may have potential for the development of new leads to treat infection caused by trypanosomes. Further comprehensive structure activity studies to clarify the contribution of sesquiterpene ring systems and/or substitution patterns of sesquiterpene lactones to the overall activity against both *T. b. rhodesiense* and mammalian cell like those reported by Schmidt et al. [23] and especially further in vivo data like Zimmermann et al. [9] are needed.

4. CONCLUSIONS AND OUTLOOK

As a result of a first screening campaign, 10 extracts, which belong to 10 different species and 7 families were chosen based on the following criteria: i) antiprotozoal activity; ii) selectivity; and iii) different genus [1]. Seventeen HPLC-based activity profiles were obtained. However, in most of the cases no activity was observed after micro-fractionation. Only the DCM extract of *Eucomis autumnalis* (flowers/buds) showed activity (90%) against *L. donovani*, but the dereplication of 4'-*O*-methyl-punctatin (homoflavonoid), as a major active compound was performed. Due to these poor results, a second screening was carried out [2]. The extracts of *Abrus precatorius*, *Clutea pulchella*, *Drypetes gerrardii*, and *Turraea floribunda* fulfilled the requirements for a follow up by HPLC-based activity profiling. Eighteen HPLC-based activity profiles were obtained by analytical separation of sub-milligram amounts of the extracts. Activity profiles of *A. precatorius*, *C. pulchella*, and *D. gerrardii* exhibited antiprotozoal inhibition of greater than 50%.

Abrunone B was dereplicated from the *A. precatorius* HPLC-activity profile. Nevertheless, the chromatogram showed additionally active peaks. Consequently, this extract was prioritized. No records were found for peaks present in the active windows of the HPLC-activity profiles of *D. gerrardii* and *C. pulchella*. Hence, the extracts were also prioritized in the mentioned order.

Preparative isolation of active compounds to perform structure elucidation and *in vitro* test was achieved. Thanks to the combination of chromatographic techniques such as flash chromatography and semi-preparative HPLC chromatography, only a small amount of crude extracts (1.0 g) from *A. precatorius* (Batch I) and *D. gerrardii* was needed to obtain compounds in multi-milligram amounts. Structures were elucidated by HR-ESIMS, and 1D and 2D NMR (^1H , ^{13}C , COSY, HMBC, HSQC, and NOESY) spectroscopy by using a 500 MHz spectrometer equipped with 1mm microprobe. When new chiral compounds were found, their absolute configuration was determined by comparison of the electronic circular dichroism (ECD) spectra with calculated ECD.

In addition to South African plants, some European plants such as, *Chrysanthemum cinerariifolium*, *Laurus nobilis*, and *Eupatorium cannabinum* were investigated. Nine compounds were isolated from these plants.

In total, 22 secondary metabolites were isolated. Their *in vitro* antiprotozoal activity and selectivity are listed in Table 6. Following the criteria of activity and selectivity of the Swiss TPH (see Table 5), 15 compounds showed parasite inhibition to some extent, ranging from active to moderately active. The remaining 7 compounds exhibited no activity against the mentioned parasites. The selectivity was calculated by dividing the IC_{50} value for L6 cells by the IC_{50} value in the parasite assay. Both, activity and

selectivity of pure substances, in addition to their structure novelty were criteria to prioritize compounds for large scale isolation to perform primary *in vivo* assays.

Pyrethrin II and Jasmolin II, isolated from *C. cinerariifolium*, showed moderate activity against *P. falciparum*, and low selectivity (IC_{50} $4.0 \pm 1.1 \mu M$ and $5.0 \pm 0.4 \mu M$, SIs of 24 and 6, respectively). Pyrethrins were inactive against *T. b. rhodesiense*. Antiprotozoal properties of pyrethrins were compared with those of pyrethroids. Albeit pyrethrins were more active than pyrethroids (IC_{50} from $8.9 \pm 2.0 \mu M$ to inactive), neither activity, nor selectivity were sufficient to warrant *in vivo* studies [3].

Sesquiterpene lactones were isolated from *L. nobilis* and *E. cannabinum* to investigate their antiprotozoal properties, and to start a structure-activity relationship study. Two germacrolides, costunolide and eupatoriopicrin, showed higher trypanocidal activity (IC_{50} of $1.3 \pm 0.4 \mu M$ and $1.2 \pm 0.2 \mu M$, respectively) than the guaianolide zaluzanin D (IC_{50} of $10.8 \mu M$) [4]. Other guaianolides, such as cynaropicrin, had shown high trypanocidal activity (IC_{50} of $0.28 \pm 0.001 \mu M$) [5]. As a result of further studies performed by our research group, it is now known that an acyl side chain at OH-8, lacking in zaluzanin D and present in cynaropicrin, is essential for such activity [6]. None of the isolated sesquiterpene lactones in this work showed sufficient activity and selectivity to pursue *in vivo* tests.

Abruquinones B and I from *A. precatorius* [7] and the phenanthrenone drypenenone D from *D. gerrardii* [8] fulfilled activity and selectivity requirements to conduct primary *in vivo* tests. Hence, a second batch of each plant was collected to perform large scale isolation since a minimum amount of 25 mg for each pure compound is needed for primary *in vivo* assays.

Phytochemical profiles of batch I and II (second recollection) from *A. precatorius* were compared. Major differences were found in their composition. Abruquinones in batch II were only detected after enrichment by flash chromatography. The isolation of five additional abruquinones was achieved, although in low quantities only. Their trypanocidal activity was assessed *in vitro* (Table 6). All five abruquinones showed remarkable and selective inhibition of *T. b. rhodesiense*. Even though the goal of a large scale isolation of abruquinones from batch II was not achieved, we were able to isolate additional active abruquinones, confirming that this class of compounds shows interesting trypanocidal activity [9]. The inhibition (ranging from 0.28 to $0.007 \mu M$) and selectivity (ranging from 51 to 1379) of active abruquinones were better than inhibition and selectivity of some lead compounds currently under clinical trials for HAT, namely fexinidazole (IC_{50} 0.7 - $3.3 \mu M$, SI >100, Phase II/III) and oxaborole SCYX-7158 (IC_{50} 0.2 – $1.0 \mu M$, SI >100, Phase I) [10, 11]. Thus the *in vivo* assessment of abruquinones is highly recommended.

^a Values are expressed as mean ± standard error of the mean. ^b No activity observed at the highest test concentration of 90 μg/mL, which corresponds to molar test concentrations of 269.4 to 220.5 μM. ^c No activity observed at the highest test concentration of 10 μg/mL, which corresponds to molar test concentrations of 24.5 to 1.29 μM. ^d Active compounds against at least one parasite.

No obvious structure activity relationship (SAR) was observed among the ten abruquinones.

Qualitative and quantitative differences in abruquinones content between batch I and II could be due to seasonal effects. Batch I was collected in summer, whereas batch II was collected in autumn. The variation in the content of abruquinone should be taken into account for further material recollection. Additionally, to assure a botanical source of abruquinones, for further phases of discovery, it is necessary to perform studies on the influence of different factors such as, environment and genetics, on the production of abruquinones [12]. Optimization of the extraction method could also be considered. Recently, a method for obtaining abruquinone A from the roots of *A. precatorius* has been patented [13].

Late approaches that endeavour to re-establish natural products in the modern, HTS-based lead discovery paradigm have focused on early compound selection driven by molecular properties associated with lead- and drug likeness [14, 15]. Some descriptors, namely Lipinski's parameters [molecular weight ≤ 500 , $\log P \leq 5$, sum of H-donors/acceptors ≤ 10], rotatable bonds (≤ 10), and polar surface area (PSA) ($\leq 60\text{-}70 \text{ \AA}^2$) can predict permeability across biological barriers [16, 17]. In general, abruquinones complied with Lipinski's "rule of 5" requirements, except for abruquinone K, for which the sum of H-donors/acceptors is 12 (Table 7). Accordingly, oral bioavailability of abruquinones can be expected, which is one of the main requirements for an antiprotozoal drug. Abruquinones also fulfil the flexibility criterion (measured as rotatable bonds), but not the PSA requirements. With a PSA higher than $60\text{-}70 \text{ \AA}^2$, blood-brain barrier (BBB) permeability might be limited [30]. In drug discovery for HAT, there is a need to find drugs acting against the second stage of the disease, when parasites have already crossed the BBB. Regardless of the high PSA of abruquinones, it is known that some flavonoids are able to reach the brain. One example is kaempferol, a flavonoid which is able to cross the BBB, despite of its high PSA (111.1 \AA^2) [14, 18].

In addition to molecular parameters, generation of early safety data is crucial to avoid failure in further steps of development [20]. There are a series of proteins involved in development of adverse effects. When the ability of a compound to bind to these proteins is simulated and quantified *in silico*, it is possible to obtain an estimated toxic potential. By using “Virtual ToxLab” technology, binding affinities of the abruquinones toward 16 target proteins were calculated and, hence, an estimated potential of endocrine and/or metabolic disruption, carcinogenicity and cardiotoxicity was obtained. The toxic potential generated must be interpreted as “toxic alerts”, i.e. compounds featuring a low toxic potential should not be interpreted as benign, as adverse effects may be mediated through other targets or might trigger undesirable effects under different conditions [21]. Results for abruquinones are shown in Table 8. According to their toxic potential, abruquinones were categorized from low to class II (TP from 0 to IV). Abruquinones which are in class 0, such as abruquinones B, A, and L are unlikely to show adverse effects, triggered by the 16 target proteins tested. Abruquinone I, and D were ranked in class II because both of them showed a high *in silico* binding to glucocorticoid receptor. This might be a potential “off-target” activity of these compounds, which should be further studied, in case the compounds show *in vivo* trypanocidal activity. Importantly, their interactions with the hERG receptor, a potassium ion channel related to cardiotoxicity, were low (ranging from no binding to an affinity of 5.40 μM).

In vitro trypanocidal activity results, together with encouraging drug-like properties, and low to moderate *in silico* predicted toxicity render abruquinones interesting hits to be pursued by medicinal chemists.

In the case of *D. gerrardii*, there were no major differences between the phytochemical profiles of the first and second batch. Thus, obtaining of sufficient amounts of drypetenone D (25 mg) for *in vivo* antimalarial tests was possible. However the compound was inactive when tested in the four-day suppressive test in mice against *P. berghei* (ANKA strain).

The failure in this animal model might be due to either low systemic exposure or/and low specific activity against the parasite. Even though *P. berghei* is the species of choice for *in vivo* screening, some specific genes of this rodent *Plasmodium* may have significantly diverged from the human pathogen. Thus, there is a risk of not identifying compounds selectively inhibiting *P. falciparum*. This is the case of diamidine derivatives, which are known to be efficacious against *P. falciparum* in humans but not against *P. berghei*. To overcome this drawback some authors propose to test failed compounds against *P. berghei* in the *Pf*-huMouse [22]. Nevertheless, ethical and economical considerations must be taken into account.

Drypenone D fulfils the established drug-likeness criteria (Table 7) and, therefore, oral bioavailability and BBB permeability can be expected. This makes feasible an oral administration, one of the desired characteristics for an ideal antimalarial drug and a potential applicability for the treatment of cerebral malaria [23].

The estimated toxic potential calculated by the “Virtual ToxLab” for drypenone D was 0.52 (Table 8). This toxic potential value categorized it as a class I compound. Drypenone D bound to the progesterone receptor with high affinity (IC_{50} of 46.8 nM). This receptor has a fundamental role during pregnancy. Since antimalarial drugs are expected to be administered in pregnant women, this aspect requires particular attention [23]. However, it is important to note that *in silico* binding affinity to hERG was low (IC_{50} of 40.2 μ M).

When applying the Medicines for Malaria Venture (MVV) compound progression criteria for drug discovery pipeline of compounds against malaria [24], drypenone D fulfils some of the requirements to become a validated hit, such as i) sufficient activity against *P. falciparum* (*in vitro* cell-based assay < 1 μ M); ii) sufficient selectivity (SI > 10); iii) drug-like properties; iv) clear identification of the botanical species which contain the active compound. However, it is still necessary to i) establish a possible SAR; ii) predict ADME properties by applying computational models and iii) guarantee a source of plant material to obtain sufficient compound for further steps. *D. gerrardii* is distributed in South Africa, Namibia, Botswana, Lesotho, Swaziland, and Zimbabwe, and occurs also in the tropical region along the eastern African coastline. Abundance of the species must be carefully evaluated, taking into

Table 8. Binding Affinity to the 16 Chosen Targets and Resulting Predicted Toxicity Potential (TP) of the Most Active and Selective Compounds

Phenanthrenones										
<i>D. gerardii</i>	Phenanthrenone ^c	6	0	3	6	1		0.52	Class I	

N: none ($IC_{50} > 100$ mM), VL: very low ($IC_{50} > 1$ mM), L: low ($IC_{50} > 10$ μ M), M: medium ($IC_{50} > 100$ nM), H: high ($IC_{50} > 1$ nM), VH: very high ($IC_{50} < 1$ nM).

TP > 0.8 (extreme, class IV), $0.7 < TP \leq 0.8$ (high, class III), $0.6 < TP \leq 0.7$ (elevated, class II), $0.5 < TP \leq 0.6$ (moderated, class I), $TP \leq 0.5$ (low, Class 0).

account that it is necessary to use stems for drypenenone D extraction, as well as the ecological impact of future recollections [25]. So far, there are no reports of any straightforward method of synthesis that allow us to use this alternative.

According to the MMV progression criteria (Table 4) [24], drypenenone D should meet the following criteria to become an early lead compound i) depress parasitemia in a mouse model. So far, this is the main drawback of drypenenone D; ii) not be toxic in mice. Drypenenone D did not show signs of toxicity when tested at 50 mg/Kg in mice; even so, an *in vivo* toxicity test should be conducted; iii) have no known toxicophores/reactive groups. So far, according to the results of the predicted *in silico* toxicity, the toxic potential of the compound is low; iv) have a known mode of action or plans in place to address this; v) be stable in mouse and human plasma; vi) offer initial SAR opportunities for chemical targets with straightforward synthesis.

ACKNOWLEDGMENTS

Today a journey comes to an end and a wish becomes true. I thank God for everything I have received. Being in Basel has meaning to me not only walking in the same streets where Paracelsus once walked, but also being in touch with the cutting edge technology in drug discovery, devoted even for the most neglected.

Foremost, I would like to express my most sincere gratitude to Prof. Dr. Matthias Hamburger for accepting me as a PhD student and for all his support and immense knowledge.

Special thanks to the teams of The Council for Scientific and Industrial Research (CSIR) and The Swiss Tropical and Public Health Institute (Swiss TPH) which were involved with this project. Especially to Gerda Fouche (CSIR), Prof. Dr. Reto Brun, and Marcel Kaiser (Swiss TPH) for their excellent work and solicitous help.

I am very grateful to the members of my defense committee for taking the time to read my document and for their valuable inputs. Particularly, Prof. Dr. Irmgard Merfort, my external co-referee and Prof. Dr. Kurt Hersberger, for acting as a moderator.

I am very grateful to Dr. Olivier Poterat for his knowledge, help, and kindness along my PhD.

My gratitude to Prof. Roberto Pinzon and Kurt Hostettmann for introduce me to Prof. Matthias Hamburger.

I would like to thank former postdocs Dr. Inken Plitzko, Dr. Janine Zaugg, Dr. Melanie Raith, and current ones, Dr. Maria De Mieri, Dr. Samad Ebrahimi, and Dr. Eliane Garo for helping me to build my knowledge every day.

Special thanks to:

Manuela Rogalski, she has encouraged me, support me, helped with all the official and administrative issues in German, proof read my documents, including this final one, shared her family and show her country to me.

Diana Rueda, who has become during this time in the sister that I hadn't have before. Thanks for the friendship, fun, embrace, and being my confidant.

Daniela Eingenmann for her friendship, kindness, support, trust, and for proof read this document with patient and dedication.

Dr. Chee Seng Hee for his friendship and kindness for proof-read, the first two chapters of the introduction of this document.

Orlando Fertig for his help and good work. All friends and current and former members of the group, for the good moments, nice work, and support. Dr. Mouhssin Oufir, Christian Abbet, Anja Schramm, Tasqiah Julianti, Teresa Falechini, Evelyn Jähne, Elisabetta Corradi, Alen Bozicevic, Niels Guldbrandsen, Justine Ramseyer, Fahime Moradi, Olga Zabelo, and Petra Weber.

My gratitude is also extended to The National University of Colombia for the “Comision de Estudios”, particularly, to The Faculty of Sciences and The Pharmacy Department for their continuous support. I would like to thank professors Ignacio Mantilla, Jesús Valencia, Julián López, Fabio Aristizabal, and Yolima Baena for their always kind support in all the administrative issues.

Next, I would like to thank Colciencias (Administrative Department of Science, Technology, and Innovation of Colombia) for my grant and Laspau for the administration of this, particularly to Lisa Tapiero.

To professor Lucía Arteaga, for being my mentor. And professors Luis Fernando Ospina, Ahmed Salama, Giovanny Garavito, Mario Guerrero, Noralba Sierra, Maria Teresa Reguero, Afife Mrad de Osorio, Gustavo Buitrago, Lucy Delgado, and Javier Rincon for their knowledge and help along my academic life.

To my uncle and professors Luisa Ponce de Leon, Pilar Luengas, Claudia Mora and Antonio Sanabria, without their trust on me and in this project this would have never be possible. For their caring and love.

To all my friends Rocio Morales, Angela Zambrano, Nadhezda Vergel, María Fernanda Zuluaga, Karen Silva, Juliana Manrique, Angelica Monsalve, Martha Suarez, Claudia Vaca, Esperanza Avella, German Matiz, Luis Franco, Claudia Cordero, Maritza Rojas, and Marcela Aragón, for their patients, love, embracing, caring, advice, and understanding.

And last but not least, my family. My mother, my uncle, and my grandmother (may she rest in peace), for their love, support, and give me all what I needed to be happy and go as far as I have wanted. Additionally, to Consuelo Guerra y Juan Carlos. To them my deepest gratitude.

Curriculum Vitae

Last Name, First Name **Hata Uribe, Yoshie Adriana**
Address **Dauidsbodenstrasse 38, CH-4056 Basel**
Telephone **0041 76 7826060**
e-mail **yoshie.hata-uribe@unibas.ch**

CURRENT POSITION

Ph D Student, Pharmaceutical Biology, University of Basel, Basel, Switzerland

EDUCATION

2009 – present Pharmaceutical Biology, University of Basel, Basel, Switzerland
PhD PHARMACEUTICAL SCIENCES

2006 – 2007 National Pedagogy University, Bogotá, Colombia
TEACHING SPECIALIZATION

2003 - 2005 National University of Colombia, Bogotá, Colombia
MAGISTER IN PHARMACEUTICAL SCIENCES

1993 – 2000 National University of Colombia, Bogotá, Colombia
PHARMACIST

WORK EXPERIENCE

March 2007 – Current	Auxiliary Lecturer and Researcher at Department of Pharmacy, Faculty of Science, National University of Colombia.
January 2004 – December 2006	Lecturer and Assistant Researcher at Department of Pharmacy, Faculty of Science, National University of Colombia.
March 2001 – December 2003	Assistant Researcher at Department of Pharmacy, Faculty of Science, National University of Colombia.
April 2000 – February 2001	Assistant Researcher at Institute of Biotechnology, National University of Colombia.

LANGUAGES

- Spanish: Mother tongue.
- English: Fluent in oral and written communication.
- German: Basics.
- Japanese: Basics.

SKILLS

Pharmacist skilled in natural product isolation, HPLC-UV-MS, NMR spectroscopy, antimalarial *in vitro* (*Plasmodium falciparum*) and *in vivo* (*Plasmodium berghei*) assays, cell culture, *in vivo*-pharmacology (anti-inflammatory rodent models and central nervous system mice models).

CONGRESSES ORAL PRESENTATIONS

- Antiprotozoal isoflavan quinones from *Abrus precatorius*. Hata Y. et al. 61th International Congress and Annual Meeting of the Society for Medicinal Plant and Natural Product Research (GA), Munster, Germany, September 1st to 5th, 2013.
- Developing of an automatic *Plasmodium falciparum* counting system and applying it to pharmacologically screening of anti-malarial plants (Desarrollo de un conteo automático de *Plasmodium falciparum* y su aplicación al screening farmacológico de plantas medicinales). García J.D., Arteaga L., **Hata Y. et al.** II National Biotechnology Congress, Bogota, Colombia, Biotechnology Institute, September 1st to September 3rd, 2004.
- Analysis of steroidal sapogenins from tubers of Colombian yam *Dioscorea* sp. from Universidad de Cordoba collection” (Cuantificación de sapogeninas esteroidales de tubérculos de ñame colombiano *Dioscorea* sp obtenidas de la colección de la Universidad de Córdoba). Buitrago G., Reguero R., Arteaga L., Álvarez A., **Hata Y.** VII National Phytochemical Congress, Bogota, Colombia. Pontificia Universidad Javeriana, April 30th to May 3rd, 2002.

CONGRESSES POSTER PRESENTATIONS

- Poster 1: Antiprotozoal compounds from *Drypetes gerrardii*. Hata Y., Ebrahimi S., De Mieri M., Zimmermann S., Mokoka T., Naidoo D., Fouche G., Maharaj V., Kaiser M., Brun R., Potterat O., Hamburger M.

Annual Research Meeting. University of Basel, Basel, Switzerland, February 10, 2014.

- Poster 2: Antiprotozoal isoflavan quinones from *Abrus precatorius*. Hata Y., Ebrahimi S., Raith M., De Mieri M., Zimmermann S., Mokoka T., Naidoo D., Fouche G., Maharaj V., Kaiser M., Brun R., Hamburger M.

Swiss Pharma Science Day 2013. University of Bern, Bern, Switzerland, August 28th, 2013.

Swiss Chemical Society - 2012 Fall Meeting. Lausanne, Switzerland, September 6th, 2013.

- Poster 3: Antiprotozoal isoflavan quinones from *Abrus precatorius ssp. africanus*. Hata Y., Raith M., Ebrahimi S., Zimmermann S., Mokoka T., Naidoo D., Fouche G., Maharaj V., Kaiser M., Brun R., Hamburger M.

International Congress on Natural Products Research. New York, USA, July 28th to August 1st, 2012.

Swiss Pharma Science Day 2012. University of Bern, Bern, Switzerland, August 29th, 2012.

13th International Congress of the Society for Ethnopharmacology. Graz, Austria, September 2nd to 6th, 2012.

Swiss Chemical Society - 2012 Fall Meeting. Zürich, Switzerland, September 12th, 2012.

Annual Research Meeting. University of Basel, Basel, Switzerland, February 14th, 2012.

- Poster 4: Antiplasmodial and antitrypanosomal activity of pyrethrins and pyrethroids. Hata Y., Zimmermann S., Brun R., Kaiser M., Hamburger M., Adams M.

Pharma Science Day 2011. University of Bern, Bern, Switzerland, September 07th, 2011.

Annual Research Meeting. University of Basel, Basel, Switzerland, February 2nd, 2011.

- Poster 5: Screening of South African medicinal plants and HPLC based profiling for the identification of leads with antiprotozoal activities. Hata Y., Julianti T., Mokoka T., Moodley N., Zimmermann S., Adams M., Brun R., Kaiser M., Hamburger M.

58th International Congress and Annual Meeting of the Society for Medicinal Plant and Natural Product Research. Freie Universität, Berlin, Germany, August 29th to September 2nd, 2010.

Swiss Pharma Science Day 2010. University of Bern, Bern, Switzerland, September 8th, 2010.

11th International Congress of the Society for Ethnopharmacology. Albacete, Spain, September 20th to 24th, 2010.

Annual Research Meeting. University of Basel, Basel, Switzerland, February, 2010.

- Poster 6: Contribution to the elaboration of a quality control monograph for *Abuta grandifolia* (Contribución al establecimiento de una monografía para el control de calidad de *Abuta grandifolia*). Hata Y., Ospina L.F., Luengas P.

X Congreso Colombiano de Fitoquímica, Popayán, Colombia, June 9th to 12th, 2009.

- Poster 7: Anti-protozoal activity of 21 Colombian medicinal plants (Actividad anti-protzoaria de 21 plantas medicinales colombianas). Hata Y., Arteaga L., Calle J., Rincón J., Pinzón R., Ruíz G., Vargas F., Gutiérrez D., Giménez A.

IX South-American Pharmaceutical Federation Congress, Bogota, Colombia October 29th to November 1st, 2004.

- Poster 8: Standardization of a hemolytic microassay for in vitro anti-complementary activity of plant extracts (Estandarización de un microensayo hemolítico in vitro para la evaluación de la actividad anti-complementaria de extractos vegetales). Arteaga L., Ortiz M., Hata Y.

VII National Phytochemical Congress, Bogota, Colombia. Pontificia Universidad Javeriana, April 30th to May 3rd, 2002.

- Poster 9: Antimalarial activity of Colombian and Panamanian plants used in folk medicine (Actividad antimalárica de plantas usadas en la medicina folclórica colombiana y panameña). Hata Y., Cifuentes L., Arteaga L., Pinzón S., Vásquez Y., Solís P., Gupta M.

I Iberoamerican Pharmaceutical Fine Chemical Congress, Salamanca, Spain, Universidad de Salamanca, April 15th to 19th, 2002.
